# 1 Introduction

Software defined networking (SDN) paradigm revolves around separation of forwarding/data plane and control plane, logically centralized control and application-focused programmable interfaces. In transport networks where logically-centralized control/management and control-data separation are not new concepts and the network-control function and behavior are well-understood and established, standardizing application programmer's interfaces (APIs) to the network control functions become important.

## 1.1 Purpose

The purpose of this document is to specify the information that is relevant to an application programmer's interface (API) to transport network-control functions and serve as a "Functional Requirements Specification" (FRS) document for the transport API work in ONF.

Since the APIs are defined at interface boundaries and are intended to mask the need to understand the internal architectures on either side of the interface boundary, the focus has been to define purpose-specific use case scenarios from an application point of view treating the API provider as a "black box". These application use cases have been used to drive the API requirements as well as to harmonize, generalize and normalize the API specifications. To facilitate the understanding of these requirements, some of the use cases are described in the appendices.

Although these requirements are based off few use cases, a key purpose is to ensure that the APIs do not limit valid application use cases not considered here.

## 1.2 Scope

Based on the use case contributions and early discussions in the ONF/OTWG "Transport API" project discussion group, this work is initially scoped to specifying APIs for the following transport network controller services:

- Topology Service
- Connectivity Service
- Path Computation Service
- Virtual Network Service
- Notification Service

For the purposes of this document, it is assumed that access control and policy details are conveyed via a sideways/orthogonal interface. It is understood that all API requests would be subject to filtering and scoping based on the privileges assigned to the calling entity and these would be based on business contracts as well as security and organizational roles. Application of such policy constraints and filtering to the API requests and responses is out of scope for this document. In other words, the API considerations in this document are from the perspective of the most privileged super-user.

### 215 1.5 Terms and Definitions

216 This section defines some key terms that aid in understating the requirements. More information  
 217 is provided in the appendices and it is recommended that the reader familiarize themselves with  
 218 the basic concepts, constructs and use cases described in those sections.

219 In general, the T-API uses terminology that is familiar to the transport network management  
 220 industry, but maps to constructs defined in the ONF Core Information Model in form of purpose-  
 221 specific realizations. So it must be noted that these definitions are neither authoritative nor  
 222 exhaustive, and the reader should refer to the realized/mapped entities defined in ONF Core  
 223 Information Model document.

224 Also it should be noted that API IM relates to information exchanged over an interface and the  
 225 entity definitions are intended to provide a logical structure for encapsulating information that is  
 226 exchanged, and not intended to specify the information model patterns for implementations on  
 227 either side of the interface.

## Context (API Context)

The T-API defines the scope of control, interaction and naming that a particular T-API provider or client application has with respect to the information exchanged over the interface. This *Context* is shared between the API provider and its client.

**Topology** The T-API *Topology* is an abstract representation of the topological-aspects of a particular set of *Network Resources*. It is described in terms of the underlying topological network of *Nodes* and *Links* that enable the forwarding capabilities of that particular set of *Network Resources*.

## Node

The T-API *Node* is an abstract representation of the forwarding-capabilities of a of a particular set of *Network Resources*. It is described in terms of the aggregation of set of ports (*Node-Edge-Point*) belonging to those *Network Resources* and the potential to enable forwarding of information between those edge ports.

## Link

The T-API *Link* is an abstract representation of the effective adjacency between two or more associated *Nodes* in a *Topology*. It is terminated by *Node-Edge-Points* of the associated *Nodes*.

## Node-Edge-Point

The T-API *Node-Edge-Point* represents the inward network-facing aspects of the edge-port functions that access the forwarding capabilities provided by the *Node*. Hence it provides an encapsulation of addressing, mapping, termination, adaptation and OAM functions of one or more transport layers (including circuit and packet forms) performed at the entry and exit points of the *Node*.

## Service-End-Point

The T-API *Service-End-Point* represents the outward customer-facing aspects of the edge-port functions that access the forwarding capabilities provided by the *Node*. Hence it provides a limited, simplified view of interest to external clients (e.g. shared addressing, capacity, resource availability, etc), that enable the clients to request connectivity without the need to understand the provider network internals. *Service-End-Point* have a mapping relationship (*one-to-one*, *one-to-many*, *many-to-many*) to *Node-Edge-Points*.<sup>1</sup>

## Connection-End-Point

The T-API *Connection-End-Point* represents the ingress/egress port aspects that access the forwarding function provided by the *Connection*. The *Connection-End-Points* have a client-server relationship with the *Node-Edge-Points*.

---

<sup>1</sup> Criteria for assigning/mapping *ServiceEndPoints* to *NodeEdgePoints* are out of scope of this FRS, but are typically part of implementation agreement (IAs) and some examples are provided by the use cases in the appendices.

## Connectivity-Service

The T-API *Connectivity-Service* represents an “intent-like” *request* for connectivity between two or more *Service-End-Points*. As such, *Connectivity-Service* is a container for connectivity request details and is distinct from the *Connection* that realizes the request

## Connection

The T-API *Connection* represents an *enabled* (provisioned) potential for forwarding (including all circuit and packet forms) between two or more *Node-Edge-Points* of a *Node*. The T-API *Connection* is terminated by *Connection-End-Points* which are clients of the associated *Node-Edge-Points*. As such, the *Connection* is a container for provisioned connectivity that tracks the state of the allocated resources and is distinct from the *Connectivity-Service* request.

## Route (Connection Route)

The T-API *Route* represents the route of a *Connection* through the lower-level *Nodes* in the underlying *Topology*. It is described as a list of references to the lower-level *Connections*.

## Path

A *Path* is described by an ordered list of *TE Links*<sup>2</sup>. A TE Link is defined by a pair of *Node/NodeEdgePoint* IDs). A *Connection* is conceptually a concatenation of link resources (associated with a *Link*) and the lower-level connections (cross-connections) in different *Nodes*.

## Virtual Network Service

The T-API *Virtual-Network-Service* (VNS) represents a request for creation and offering of a virtual network *Topology* that maps two or more *Service-End-Points*, by an API-provider to an API client in accordance with agreements reached between them (e.g., satisfying the users' objectives). As such, *Virtual-Network-Service* is a container for virtual network *Topology* request details and is distinct from the *Topology* that realizes the request.

## 1.6 Conventions

This document uses the keywords "may" and "must" to qualify optional and mandatory requirements.

---

<sup>2</sup> The TE Link here relates to the Link Ports of a P2P Link or in case of a Multipoint Link, to a single pair of Link Ports

## 2 Functional Architecture

The Transport APIs are defined in the background context of network programmability and applies SDN principles to enable cost reduction, innovation and reduced time to market of new services. It aims to achieve these goals by providing programmable access to typical transport SDN Controller functions. The Transport API abstracts a common set of control plane functions, such as Network Topology, Connectivity Requests, Path Computation and Network Virtualization to a set of Service interfaces.

These APIs are defined to be applicable on the interface between a Transport SDN controller “Black Box” and its client application. The actors involved in the information exchange over this interface include transport network provider domain controllers in the role of producers and the transport network application systems in the role of the consumers. The transport network application systems could be either a business client system (which itself may include some control functions) or the network operator’s upper level control, orchestration and/or operations systems. This includes privileged application systems that would expect access to internal views of the network model and states using these same set of APIs - for example, usage of topology APIs to access abstract/virtual network topologies provided to business clients as well the underlying actual network topology and entities to which the abstract /virtual entities are mapped. The T-APIs are also intended to be equally applicable between the controllers within a transport controller recursive hierarchy.

It is understood that the APIs are executed within a shared *Context* between the API provider and its client application. A shared *Context* models everything that exists in an API provider to support a given API client. The negotiation and setup of the shared *Context* is outside the T-API scope, but is expected to minimally involve agreement on *Service-End-Points*, its naming (TRI) and its capabilities.

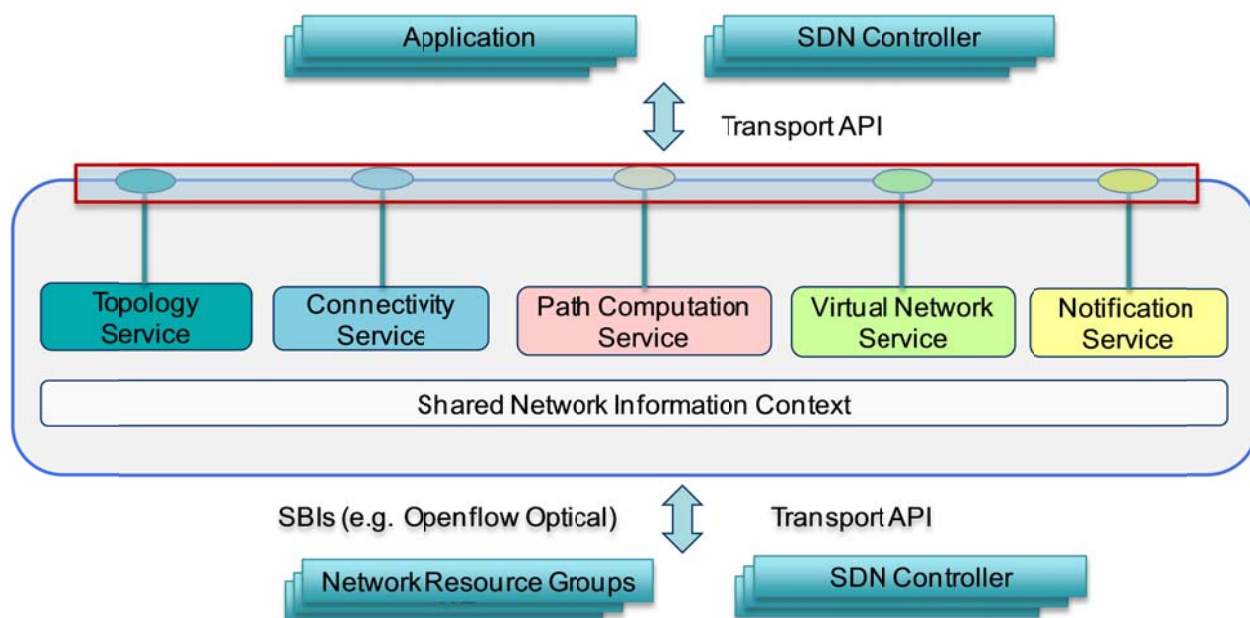

Typically, the shared *Context* setup also includes association attributes to establish identity and security that permit secure client-provider communication sessions. A session is the mechanism<sup>3</sup> that supports information exchange between specific instances of an API client and an API provider within a shared *Context* that has been secured by appropriate authentication and security credentials and prevents unauthorized access. Similar to user login, the session normally begins with an exchange of identity and security credentials, followed by agreement on an initial state, much of which may be re-stored from prior sessions. During the session, the API client may invoke services on and modify the state of resources within the shared *Context*. Each information exchange should be attributable to a session, for example in an audit log. A session may continue indefinitely, or end with an explicit logout, a failure, or a timeout. Since the shared *Context* supports only one session (or vice-versa), the session identification and association with the shared *Context* is implicit.

Thus a shared *Context* determines the makeup of the network resource abstraction instances over which the API operates. For example, the API client could

---

<sup>3</sup> The actual implementation-specific mechanisms to maintain, exchange or enforce the session state information is out of scope of this document and could be either maintained by the stateful API provider/server or offered by the API clients (as in stateless RESTful communication architectures)

- Request retrieval of the *Service End Points* in the shared *Context*
- Request creation of a *Connectivity Service* between the *Service End Points* – these operations can be performed without the knowledge of *Network Topology* or with the knowledge of the *Topology* (using *Topology* retrieval APIs)
- Request creation/modification of *Virtual Network Topology* within the shared context
- Request retrieval of the (Virtual) *Network Topology* - either provider-assigned (by offline/external means) or client-created- (using *VN Service API*) within the shared context

**Figure 1: Transport API Functional Architecture**

## 3 Functional Requirements

### 3.1 Topology Service

#### 3.1.1 Topology Retrieval APIs

TAPI_FR 1: Get Topology List	
<b>Description</b>	<ul style="list-style-type: none"> <li>Returns list of top-level <i>Topology</i> instances directly scoped by the <i>Context</i></li> <li>This also includes details for each <i>Topology</i> including references to lower-level <i>Nodes</i> and <i>Links</i> encompassed by the <i>Topology</i></li> </ul>

### 3.3 Path Computation Service

The APIs in this section have been defined making certain assumptions on the division of responsibilities and sequence flow of interactions between different T-API Service interfaces. For example, it is assumed that a connection control module that handles the *ConnectivityService* request, is in charge of the management and implementation of the *Connections* in terms of real resource commitment for the routes (*Paths*) of an *Connection*. In contrast, a routing control module that handles the *PathComputationService* requests (from the internal connection-control module or external applications) is responsible for computing and providing the *Paths* for a potential *Connection* as output.

#### 3.3.1 Path Computation Request APIs

TAPI_FR 15: Compute P2P Path	
<b>Description</b>	Path computation can be called in the context of service request since path computation is provided in a domain according to the policy which has to refer to specification of service for which the path computation request is required. The client side of the API can request the server side of the API to compute a single path or a batch of paths with consideration of a set of constraints
<b>Pre-conditions</b>	The server side of this API should have the topology information (including TE information) of the network in which the path computation applies. Includes Connectivity matrix, port label restriction (only applicable to optical layer path computation)
<b>Inputs</b>	<ul style="list-style-type: none"> <li>List of following details for every<sup>4</sup> <i>ServiceEndPoint</i> for the <i>ConnectivityService</i> <ul style="list-style-type: none"> <li>Role<sup>5</sup> of the terminating <i>ServiceEndPoint</i> in the context of the <i>Service</i></li> <li>Directionality of the terminating <i>ServiceEndPoint</i> in the context of the <i>Service</i></li> <li>Reference (Name/ID) to terminating <i>ServiceEndPoint</i></li> <li>Optionally the Layer of the <i>ServiceEndPoint</i> if it supports multiple layers</li> </ul> </li> <li>Routing (Connectivity) Constraints including <ul style="list-style-type: none"> <li>Required Constraints such as Capacity</li> <li>Optional Constraints such as Layer, Latency, Cost, etc</li> </ul> </li> <li>Objective function</li> </ul>

<sup>4</sup> The number of ServiceEndPoints is restricted to 2 for the Path Computation request

<sup>5</sup> The value for Role is constrained to only Symmetric for the Path Computation request

<b>Outputs</b>	List of paths computed containing following information (only “one” if shouldComputeConcurrentPaths is false) <ul style="list-style-type: none"> <li>Path identifier (identifier of the calculated route )</li> <li>Routing constraints (Description of connectivity constraints that are met)</li> <li>Path which is an ordered list of TE Links – described either as strict hops (NodeEdgePoints) or loose hops(Nodes )</li> </ul>
<b>Notifications</b>	<ul style="list-style-type: none"> <li><i>ObjectCreation</i> notifications on <i>computed/created Paths</i></li> </ul>
<b>Error-conditions</b>	Cause of failure
<b>Post-conditions</b>	
<b>Sources</b>	Oif Onf IETF

371

TAPI_FR 16: Optimize P2P Path	
<b>Description</b>	A connection can be reconfigured to meet new constraints and achieve path optimization via this API. Reconfiguration may involve intermediate-point changes and route changes
<b>Pre-conditions</b>	The server side of this API should have the topology information (including TE information) of the network in which the path computation applies
<b>Inputs</b>	<ul style="list-style-type: none"> <li>Path Id: Identifier of path to be modified</li> <li>Connection Id: (optional) Identifies resources in use for the Connection for the path being optimized</li> <li>Routing (Connectivity) Constraints including <ul style="list-style-type: none"> <li>Required Constraints such as Capacity</li> <li>Optional Constraints such as Layer, Latency, Cost, etc</li> </ul> </li> <li>Objective Function</li> <li>Optimization Constraint</li> </ul>
<b>Outputs</b>	List of paths computed containing following information (only “one” if shouldComputeConcurrentPaths = false) <ul style="list-style-type: none"> <li>Path identifier (identifier of the calculated route )</li> <li>Routing constrains (Description of connectivity constraints that are met)</li> <li>Path which is an ordered list of (TE Links) – described either as strict hops (NodeEdgePoints) or loose hops(Nodes )</li> </ul>
<b>Notifications</b>	<ul style="list-style-type: none"> <li><i>AttributeValueChange</i> notifications on affected <i>Paths</i></li> </ul>
<b>Error-conditions</b>	Cause of failure: <ul style="list-style-type: none"> <li>Optimization fail due to insufficient resources</li> <li>Cannot readjust resource allocation without interruption of existing services.</li> <li>Cannot satisfy other constraints, such as timing issue or performance threshold.</li> </ul>
<b>Post-conditions</b>	
<b>Sources</b>	Oif Onf IETF

## 372 3.4 Virtual Network Service

### 373 3.4.1 Virtual Network Retrieval APIs

TAPI_FR 17: Get Virtual Network Service List	
<b>Description</b>	<ul style="list-style-type: none"> <li>Returns list of <i>VirtualNetworkService</i> entities that represent the virtual network requests that were received</li> <li>This also includes attribute details for each <i>VirtualNetworkService</i> including <ul style="list-style-type: none"> <li>References to <i>ServiceEndPoints</i> of the <i>Service</i></li> <li>Optionally, references to the virtual <i>Topology</i> realizing the <i>VirtualNetworkService</i></li> </ul> </li> </ul>
<b>Pre-conditions</b>	
<b>Inputs</b>	<ul style="list-style-type: none"> <li>Retrieve Scope Filter: <i>Layer-Protocol</i> List : Enumeration value <ul style="list-style-type: none"> <li>If set/non-empty, the API call will return references to only those encompassed <i>VirtualNetworkServices</i> that support at least one of the specified layer protocols</li> </ul> </li> <li>Include <i>Topology</i> : true or false</li> </ul>
<b>Outputs</b>	List of <i>VirtualNetworkServices</i> indexed by <i>Layer</i> and details for each including: <ul style="list-style-type: none"> <li>List of IDs, Names, Labels and Extensions (if any)</li> <li>Administrative, Operational, and Lifecycle States</li> <li>Virtual Network Constraints including <ul style="list-style-type: none"> <li>Required Constraints such as Service Level and Traffic Matrix</li> <li>Any optional Constraints</li> </ul> </li> <li>Optionally the <i>Topology</i> realizing the <i>VirtualNetworkService</i></li> </ul>
<b>Notifications</b>	
<b>Error-conditions</b>	
<b>Post-conditions</b>	
<b>Sources</b>	TBD

374

TAPI_FR 18: Get Virtual Network Service Details	
<b>Description</b>	<ul style="list-style-type: none"> <li>Returns attributes of the <i>VirtualNetworkService</i> entity identified by the provided inputs.</li> <li>This includes references to <i>ServiceEndPoints</i> of the <i>VirtualNetworkService</i>.</li> <li>This optionally includes references to the <i>Topology</i> realizing the <i>VirtualNetworkService</i>.</li> </ul>
<b>Pre-conditions</b>	
<b>Inputs</b>	<ul style="list-style-type: none"> <li><i>Service</i> ID or Name : String <ul style="list-style-type: none"> <li>When NULL is provided, this API call should return an error condition</li> </ul> </li> <li>Include <i>Topology</i> : true or false</li> </ul>
<b>Outputs</b>	<ul style="list-style-type: none"> <li>List of IDs, Names, Labels and Extensions (if any)</li> <li>Administrative, Operational, and Lifecycle States</li> <li>Virtual Network Constraints including <ul style="list-style-type: none"> <li>Required Constraints such as Service Level and Traffic Matrix</li> <li>Any optional Constraints</li> </ul> </li> <li>Optionally the <i>Topology</i> realizing the <i>VirtualNetworkService</i></li> </ul>

### 3.4.2 Virtual Network Request APIs

TAPI_FR 19: Create Virtual Network Service	
<b>Description</b>	For the client side of the API to request creation of a virtual network from a network (maybe physical or virtual network, recursively) provided by the server side of this API, according to the traffic volume between the access points of the client. As a result, the server side of this API will reserve a set of resources to build up the virtual network, over which the client side of the API is allowed to e.g. configure virtual connections (through other transport APIs).
<b>Pre-conditions</b>	The server side of this API should have the topology information of the network under its control.
<b>Inputs</b>	<ul style="list-style-type: none"> <li>List of following details for every <i>ServiceEndPoint</i> for the <i>Virtual Network Service</i> <ul style="list-style-type: none"> <li>Reference (Name/ID) to the <i>ServiceEndPoint</i></li> </ul> </li> <li>Virtual Network Constraints including <ul style="list-style-type: none"> <li>Required Constraints such as Traffic Matrix</li> <li>Any optional Constraints such as Service Level</li> </ul> </li> <li>Start Time &amp; End Time</li> </ul>
<b>Outputs</b>	<ul style="list-style-type: none"> <li>Virtual Network Service ID: The identifier of the Virtual Network Service instance that was created that includes identifier/reference of the virtual <i>Topology</i> that was created.</li> </ul>
<b>Notifications</b>	<ul style="list-style-type: none"> <li><i>ObjectCreation</i> notifications on <i>VirtualNetworkService</i>, and associated/created <i>Topology</i>, <i>Nodes</i>, <i>Links</i> and <i>NodeEdgePoints</i></li> <li><i>AttributeValueChange</i> notifications on affected <i>ServiceEndPoints</i></li> <li><i>StateChanges</i> on related <i>State</i> attributes in the affected objects</li> </ul>
<b>Error-conditions</b>	<ul style="list-style-type: none"> <li>There are not enough resources to set up the virtual network that meets the client traffic requirement.</li> </ul>
<b>Post-conditions</b>	<ul style="list-style-type: none"> <li>The server side of this API reserves a set of resources to build up the virtual network.</li> <li>The server side of this API maintains the resources and the status of the created virtual networks, as well as the mapping relationship between the created virtual networks and the network under control of the server side.</li> <li>The client side of this API is allowed to have virtual connection control over the virtual network.</li> </ul>
<b>Sources</b>	TBD

TAPI_FR 20: Delete Virtual Network Service	
<b>Description</b>	For the client side of the API to delete the <i>VirtualNetworkService</i> and the associated <i>Topology</i> that it owns. As a result, the server side of this API will release the resources used by this virtual network.
<b>Pre-conditions</b>	<ul style="list-style-type: none"> <li>The server side of this API has the topology information of the network under its control.</li> <li>The client side of this API has requested a virtual network from the server side of this API.</li> <li>All virtual connections in the virtual network should be deleted by the client before deleting the virtual network.</li> </ul>
<b>Inputs</b>	<ul style="list-style-type: none"> <li>Virtual Network Service ID: The identifier of the virtual network to be deleted</li> </ul>
<b>Outputs</b>	<ul style="list-style-type: none"> <li>Id <i>VirtualNetworkService</i> that was deleted</li> </ul>
<b>Notifications</b>	<ul style="list-style-type: none"> <li><i>ObjectDeletion</i> notifications on <i>VirtualNetworkService</i>, and associated/deleted <i>Topologies</i>, <i>Nodes</i>, <i>Links</i> and <i>NodeEdgePoints</i></li> <li><i>AttributeValueChange</i> notifications on affected <i>ServiceEndPoints</i></li> <li><i>StateChanges</i> on related <i>State</i> attributes in the affected objects</li> </ul>
<b>Error-conditions</b>	<ul style="list-style-type: none"> <li>The requested VN (to be deleted) ID does not exist at the server side.</li> <li>One or more virtual connections remain in the virtual network.</li> </ul>
<b>Post-conditions</b>	<ul style="list-style-type: none"> <li>The server side of this API releases the resources used by the virtual network.</li> </ul>
<b>Sources</b>	TBD

### 379 3.5 Notification Service

380 Notifications refer to the set of autonomous messages that provide information about events, for  
 381 example, alarms, performance monitoring (PM) threshold crossings, object creation/deletion,  
 382 attribute value change (AVC), state change, etc. In some standards, notifications are referred to  
 383 as event reports. The specification of functional requirements for Alarms (FM) and TCAs (PM)  
 384 notifications will be provided in the next release of this document.

385 Notifications specifications are generally written around a model of a manager and an agent. The  
 386 term manager is used to designate an entity that governs notification subscriptions and receives  
 387 notification messages, while the term agent is used to designate an entity that recognizes events,  
 388 turns them into notification messages, and transmits them to pertinent subscribers. Thus, the  
 389 agent represents (acts on behalf of) managed objects that are subject to events, and emits  
 390 notification messages to inform zero or more managers (receiving entities) of these events. The  
 391 manager-agent terminology is being retained for compatibility with existing standards; however,  
 392 there is no intention to imply a distinction between management and control.

393 Notifications may be separated into two classes, primitive notifications (which are defined as)  
 394 from managed object instances to agents, and those that are processed and emitted by the  
 395 notifications agents into a form suitable for exposure to some managed object instance  
 396 (subscriber). A notification agent (NA) is modeled as the publisher of notification messages, to  
 397 any number of subscription target destinations. Examples of further processing include  
 398 interpretation, correlation, filtering, embellishment with time stamp, sequence number, system  
 399 and managed object identifier. Primitive notifications are out of scope of this document.

### 3.5.1 Notification Subscription and Filtering APIs

Notifications shall follow a publish and subscribe model. A notifications manager shall be able to create, query, modify, suspend, resume and delete a notifications subscription. The notifications available to a manager for subscription are bounded by the (virtual) resources and privileges visible to that manager. Subscriptions shall not time out and be automatically deleted during the lifetime of a given session<sup>6</sup>.

It will also be possible to retrieve notification records at a later time, by querying the notifications manager for the history records of the generated notifications. This result of the query depends on other configuration policies such as the record retention policies, which are currently out of the scope of this document.

Knowledge of available notifications and their sources is a precondition for subscription. A notifications agent shall permit a notifications manager to discover its supported notification types. Particularly in the case of virtualized resources of SDN, notifications discovery may be a feature of a general resource discovery mechanism.

Notification subscribers specify their interest according to filter, where a filter is any combination of (event related) criteria that can be unambiguously evaluated against an input to produce an accept/reject result. A filter is an attribute of a subscription, and may be modified over the lifetime of the subscription. Filters do not exist as separate managed object instances, are local to one subscription, and do not survive the deletion of that subscription. The actual notifications delivered to a target are those that pass the subscription filter.

**TAPI\_FR 21: Discover Supported Notification Types**

<b>Description</b>	Allows an API Client to discover the notifications capabilities supported by an API Provider
<b>Pre-conditions</b>	Knowledge of the Notification Server (e.g. URI, IP/Port, etc)
<b>Inputs</b>	
<b>Outputs</b>	<ul style="list-style-type: none"> <li>Supported <i>Notification-Type</i> List : Enumeration value The notification types are specified in section 3.5.2.</li> <li>Supported <i>Object-Type</i> List : Enumeration value The object types are specified in section 3.5.2.</li> </ul>
<b>Notifications</b>	
<b>Error-conditions</b>	Reason for Failure
<b>Post-conditions</b>	Supported notification and object types discovered
<b>Sources</b>	

<sup>6</sup> A session is the mechanism that supports information exchange between specific instances of an API client and an API provider within a shared Context that has been secured by appropriate authentication and security credentials.

TAPI_FR 22: Create Notification Subscription	
<b>Description</b>	Allows an API Client to subscribe to receive autonomous notifications from API provider, as per the specified filters
<b>Pre-conditions</b>	Knowledge of available notifications types and their sources
<b>Inputs</b>	<ul style="list-style-type: none"> <li>Subscription Scope Filter: <i>Notification-Type</i> List : Enumeration value. If set/non-empty, the system will push <i>Notifications</i> of one of the specified notification types only. The notification types are specified in section 3.5.2.</li> <li>Subscription Scope Filter: <i>Object-Type</i> List : Enumeration value. If set/non-empty, the system will push <i>Notifications</i> related to one of the specified object types only. The object types are specified in section 3.5.2.</li> <li>Subscription Scope Filter: <i>Layer-Protocol</i> List : Enumeration value. If set/non-empty, the system will push <i>Notifications</i> related to one of the specified layer protocols only. The layer protocols are specified in section 3.5.2.</li> <li>Subscription Scope Filter: <i>Object-Id</i> List : List of globally unique object Ids (uuid). If set/non-empty, the system will push <i>Notifications</i> related to the specified Object instances only, irrespective of other filter attribute settings</li> </ul>
<b>Outputs</b>	subscriptionId
<b>Notifications</b>	notificationId Object Creation Notification per the successful subscription.
<b>Error-conditions</b>	Reason for Failure
<b>Post-conditions</b>	Subscription created
<b>Sources</b>	

422

TAPI_FR 23: Modify Notification Subscription	
<b>Description</b>	Allows an API Client to modify its subscription to receive autonomous notifications from API provider, as per the specified filters
<b>Pre-conditions</b>	Knowledge of available notifications subscriptions, types and their sources
<b>Inputs</b>	<ul style="list-style-type: none"> <li>Subscription Id: String</li> <li>Subscription Scope Filter: <i>Notification-Type</i> List : Enumeration value. If set/non-empty, the system will push <i>Notifications</i> of one of the specified notification types only. The notification types are specified in section 3.5.2.</li> <li>Subscription Scope Filter: <i>Object-Type</i> List : Enumeration value. If set/non-empty, the system will push <i>Notifications</i> related to one of the specified object types only. The object types are specified in section 3.5.2.</li> <li>Subscription Scope Filter: <i>Layer-Protocol</i> List : Enumeration value. If set/non-empty, the system will push <i>Notifications</i> related to one of the specified layer protocols only. The layer protocols are specified in section 3.5.2.</li> <li>Subscription Scope Filter: <i>Object-Id</i> List : List of globally unique object Ids (uuid). If set/non-empty, the system will push <i>Notifications</i> related to the specified Object instances only, irrespective of other filter attribute settings</li> </ul>
<b>Outputs</b>	subscriptionId
<b>Notifications</b>	notificationId Object Creation Notification per the successful subscription.
<b>Error-conditions</b>	Reason for Failure
<b>Post-conditions</b>	Subscription created

<b>Sources</b>	
----------------	--

<b>TAPI_FR 24: Delete Notification Subscription</b>	
<b>Description</b>	Allows an API Client to delete its subscription to stop receiving autonomous notifications from API provider
<b>Pre-conditions</b>	Knowledge of available notification subscriptions
<b>Inputs</b>	<ul style="list-style-type: none"> <li>Subscription Id: String.</li> </ul>
<b>Outputs</b>	SubscriptionId of the notification subscription that was deleted
<b>Notifications</b>	Object Deletion Notification per the successful subscription.
<b>Error-conditions</b>	Reason for Failure
<b>Post-conditions</b>	Subscription deleted
<b>Sources</b>	

<b>TAPI_FR 25: Suspend Notification Subscription</b>	
<b>Description</b>	Allows an API Client to modify its subscription to temporarily stop receiving autonomous notifications from API provider
<b>Pre-conditions</b>	Knowledge of available notification subscriptions The notification subscription is active and not suspended
<b>Inputs</b>	<ul style="list-style-type: none"> <li>Subscription Id: String.</li> </ul>
<b>Outputs</b>	SubscriptionId of the notification subscription that was suspended
<b>Notifications</b>	State Change Notification per the successful subscription suspension.
<b>Error-conditions</b>	Reason for Failure
<b>Post-conditions</b>	Subscription suspended
<b>Sources</b>	

<b>TAPI_FR 26: Resume Notification Subscription</b>	
<b>Description</b>	Allows an API Client to modify its subscription to resume receiving autonomous notifications from API provider
<b>Pre-conditions</b>	Knowledge of available notification subscriptions The notification subscription is suspended
<b>Inputs</b>	<ul style="list-style-type: none"> <li>Subscription Id: String.</li> </ul>
<b>Outputs</b>	SubscriptionId of the notification subscription that was resumed
<b>Notifications</b>	State Change Notification per the successful subscription that was resumed
<b>Error-conditions</b>	Reason for Failure
<b>Post-conditions</b>	Subscription resumed
<b>Sources</b>	

TAPI_FR 27: Retrieve Notification Records	
<b>Description</b>	Allows an API Client to retrieve notification records by querying the API provider for records of the generated notifications. This result of the query depends on other configuration policies such as the record retention policies, which are currently out of the scope of this document.
<b>Pre-conditions</b>	Knowledge of available notifications types and their sources Knowledge of any Record retention policies that affect the availability of the queried <i>Notification</i> records.
<b>Inputs</b>	<ul style="list-style-type: none"> <li>Subscription Scope Filter: <i>Notification-Type</i> List : Enumeration value. If set/non-empty, the system will push <i>Notifications</i> of one of the specified notification types only. The notification types are specified in section 3.5.2.</li> <li>Subscription Scope Filter: <i>Object-Type</i> List : Enumeration value. If set/non-empty, the system will push <i>Notifications</i> related to one of the specified object types only. The object types are specified in section 3.5.2.</li> <li>Subscription Scope Filter: <i>Layer-Protocol</i> List : Enumeration value. If set/non-empty, the system will push <i>Notifications</i> related to one of the specified layer protocols only. The layer protocols are specified in section 3.5.2.</li> <li>Subscription Scope Filter: <i>Object-Id</i> List : List of globally unique object Ids (uuid). If set/non-empty, the system will push <i>Notifications</i> related to the specified Object instances only, irrespective of other filter attribute settings</li> <li>Start Time &amp; End Time – Returns all <i>Notifications</i> whose <i>Event-Time</i> falls under this range. This operation ignores the existence of any record retention policies and assumes knowledge of those policies via external means.</li> </ul>
<b>Outputs</b>	List of Notification records
<b>Notifications</b>	
<b>Error-conditions</b>	Reason for Failure
<b>Post-conditions</b>	Subscription created
<b>Sources</b>	

427

428 **3.5.2 Notification Message Types**

TAPI_FR 28: Object Creation Notification	
<b>Description</b>	
<b>Values</b>	This message shall minimally support the following attributes <ul style="list-style-type: none"> <li>Notification Header (as per above)</li> <li>Additional Information</li> <li>Additional Text</li> </ul>
<b>Sources</b>	ITU-T M.3702

429

TAPI_FR 29: Object Deletion Notification	
<b>Description</b>	

<b>Values</b>	This message shall minimally support the following attributes <ul style="list-style-type: none"> <li>• Notification Header (as per above)</li> <li>• Additional Information</li> <li>• Additional Text</li> </ul>
<b>Sources</b>	ITU-T M.3702

430

<b>TAPI_FR 30: Attribute Value Change Notification</b>	
<b>Description</b>	
<b>Values</b>	This message shall minimally support the following attributes <ul style="list-style-type: none"> <li>• Notification Header (as per above)</li> <li>• Attribute Value Change List each consisting of <ul style="list-style-type: none"> <li>○ { attributeName, oldAttributeValue, newAttributeValue }</li> </ul> </li> <li>• Additional Information</li> <li>• Additional Text</li> </ul>
<b>Sources</b>	ITU-T M.3702

431

<b>TAPI_FR 31: State Change Notification</b>	
<b>Description</b>	
<b>Values</b>	This message shall minimally support the following attributes <ul style="list-style-type: none"> <li>• Notification Header (as per above)</li> <li>• State Change List each consisting of <ul style="list-style-type: none"> <li>○ { attributeName, oldStateValue, newStateValue }</li> </ul> </li> <li>• Additional Information</li> <li>• Additional Text</li> </ul>
<b>Sources</b>	ITU-T M.3702

432

## 433 3.6 TAPI Data Types

434 This section identifies the data types, formats and values commonly associated with the  
435 parameters of the various TAPI service interface APIs.

<b>TAPI_FR 32: Layer Protocol Name</b>	
<b>Values</b>	The Layer-Protocol attribute shall minimally support following for Connectivity layers <ul style="list-style-type: none"> <li>• OCH</li> <li>• ODU</li> <li>• ETH</li> <li>• MPLS-TP</li> </ul>

436

TAPI_FR 33: Capacity (Fixed Bandwidth)	
Values	<p>The Capacity (Bandwidth) attribute is applicable for digital layers and shall minimally support following values in Mbps</p> <ul style="list-style-type: none"> <li>• 10 (Ethernet Lan)</li> <li>• 100 (Fast Ethernet)</li> <li>• 1000 (Gigabit Ethernet)</li> <li>• 2400 (ODU1/OTU1)</li> <li>• 10000 (10GBE/ODU2/OTU2)</li> <li>• 40000 (40GBE/ODU3/OTU3)</li> <li>• 100000 (100GBE/ODU4/OTU4)</li> </ul>

437

TAPI_FR 34: Capacity (Range)	
Values	<ul style="list-style-type: none"> <li>• TBD</li> </ul>

438

TAPI_FR 35: Administration State	
Values	<ul style="list-style-type: none"> <li>• LOCKED</li> <li>• UNLOCKED</li> </ul>

439

TAPI_FR 36: Operational State	
Values	<ul style="list-style-type: none"> <li>• ENABLED</li> <li>• DISABLED</li> </ul>

440

TAPI_FR 37: Lifecycle State	
Values	<ul style="list-style-type: none"> <li>• PLANNED</li> <li>• POTENTIAL</li> <li>• INSTALLED</li> <li>• IN_CONFLICT</li> <li>• PENDING_REMOVAL</li> </ul>

441

TAPI_FR 38: Port Role	
Values	<p>Denotes the role of the <i>End-Point</i> with respect to the <i>Forwarding-Construct</i></p> <ul style="list-style-type: none"> <li>• Symmetric</li> <li>• Root</li> <li>• Leaf</li> </ul>

442

**TAPI\_FR 39: Port Direction**

<b>Values</b>	Denotes the directionality of the signal-flow in the <i>Port</i> with respect to the <i>Forwarding-Construct</i> <ul style="list-style-type: none"><li>• Input</li><li>• Output</li><li>• Bidirectional</li></ul>
---------------	---

443

**TAPI\_FR 40: Termination Direction**

<b>Values</b>	Denotes the directionality of the signal-flow in the <i>ServiceEndPoint</i> or <i>ConnectionEndPoint</i> <ul style="list-style-type: none"><li>• Sink</li><li>• Source</li><li>• Bidirectional</li></ul>
---------------	--

444

**TAPI\_FR 41: Service End Point TRI format**

<b>Values</b>	The End-Point Name shall minimally support following formats <ul style="list-style-type: none"><li>• TRI</li><li>• URI</li><li>• Domain-specific String</li></ul> The formats for the TRI is out of scope for this FRS and is typically part of the implementation agreements (IAs)
---------------	---

445

**TAPI\_FR 42: Service Type**

<b>Values</b>	The Service Type attribute shall minimally support following values <ul style="list-style-type: none"><li>• POINT_TO_POINT</li><li>• POINT_TO_MULTIPPOINT</li><li>• MULTIPPOINT</li></ul>
---------------	---

446

TAPI_FR 43: Connectivity Constraints	
Values	<p>The following are the required Connectivity parameters</p> <ul style="list-style-type: none"> <li>• Service Type: The type of connectivity requested</li> <li>• Capacity: Requested bandwidth (fixed or range)</li> </ul> <p>The following are the optional Connectivity constraint parameters</p> <ul style="list-style-type: none"> <li>• Service Layer: Represents the layer of transported service</li> <li>• Service Level Descriptor– a abstract label the meaning of which is mutually agreed – typically represents metrics such as - Class of service, priority, resiliency, availability</li> <li>• Latency – integer value and unit - upper bound</li> <li>• Cost – Vector of one or more metrics that would enable the provider to make a decision when implementing the Service</li> <li>• SRLG /Diversity – an exclude Service ID – indicates that the requested service should be diverse (not share resources) from specified service</li> <li>• Include <i>Path</i> – indicates partial or complete set of nodes and/or NodeEdgePoints to be used (TE Links)</li> <li>• Exclude <i>Path</i> - indicates partial set of nodes and/or NodeEdgePoints to be avoided</li> </ul>

447

TAPI_FR 44: Virtual Network Service Constraints	
Values	<p>The following are the required Virtual Network Service parameters</p> <ul style="list-style-type: none"> <li>• Traffic Matrix: A matrix to describe the traffic (e.g., bandwidth) between each pair of ServiceEndpoints</li> </ul> <p>The following are the optional Virtual Network constraint parameters</p> <ul style="list-style-type: none"> <li>• VN Service Level Descriptor – a abstract label the meaning of which is mutually agreed – typically represents metrics such as – type of topology abstraction, class of service, priority, resiliency, availability</li> </ul>

448

TAPI_FR 45: Traffic Matrix	
Values	<p>The <i>Traffic Matrix</i> consists of a list of elements, each describing possible individual traffic flow comprising the matrix, including:</p> <ul style="list-style-type: none"> <li>• <i>ServiceEndPoint</i> details for the <i>Traffic flow</i> <ul style="list-style-type: none"> <li>• Reference (Name/ID) to the Source <i>ServiceEndPoint</i></li> <li>• Reference (Name/ID) to the Sink <i>ServiceEndPoint</i></li> <li>• Optionally the Layer of the <i>ServiceEndPoint</i> if it supports multiple layers</li> </ul> </li> <li>• Traffic Constraints including           <ul style="list-style-type: none"> <li>• Required Constraints such as Capacity</li> <li>• Optional Constraints such as Layer, Latency, Cost, etc</li> </ul> </li> </ul>

449

**TAPI\_FR 46: Path Optimization Constraint**

<b>Values</b>	<p>The following are the optimization constraint parameters to be provided as input to the Path Optimization API</p> <ul style="list-style-type: none"> <li>• Whether traffic interruption allowed or not</li> </ul>
---------------	--

450

**TAPI\_FR 47: Path Objective Function**

<b>Values</b>	<p>The following are the Objective Function parameters to be provided as input to the Path Computation Service API</p> <ul style="list-style-type: none"> <li>• Allow to compute concurrent Paths or not</li> <li>• Minimize the cost</li> <li>• Resource sharing (max re-usage/min re-usage) Whether new resource can be used or no</li> <li>• Minimum/maximum link utilization value</li> <li>• Maximize the amount of successfully computed paths (Only for concurrent path computation)</li> <li>• Minimize aggregate Bandwidth Consumption (Only for concurrent path computation)</li> <li>• Minimize the load of the Most Loaded Link (Only for concurrent path computation)</li> <li>• Minimize Cumulative Cost of a set of paths (Only for concurrent path computation)</li> </ul>
---------------	--

451

**TAPI\_FR 48: Notification-Header**

<b>Description</b>	All notifications shall contain a common header that identifies the type of the notification, the producer of the notification (object class, object instance), the time at which the underlying event occurred, a unique notification identifier, and the object instance identifier of the system hosting the agent.
<b>Values</b>	<p>This header shall minimally support the following attributes</p> <ul style="list-style-type: none"> <li>• Notification Identifier (uuid)</li> <li>• Notification Type</li> <li>• Object Type</li> <li>• Object Instance Identifier (uuid) – Globally unique ID of the object on which this notification is being raised</li> <li>• Object Instance Name List</li> <li>• Event Time Stamp</li> <li>• Notification Source Indicator</li> </ul>

452

**TAPI\_FR 49: Notification-Type**

<b>Description</b>	Notification agents shall classify notification messages into notification types; additional notification types may be defined as needed.
--------------------	---

<b>Values</b>	This enumeration shall minimally support following values <ul style="list-style-type: none"><li>• Object Creation</li><li>• Object Deletion</li><li>• Attribute Value Change</li><li>• State Change</li></ul>
---------------	---

453

<b>TAPI_FR 50: Object-Type</b>	
<b>Description</b>	Notification agents shall identify the type of the object on which a notification is raised and allow filtering of the notifications based on object types; additional object types may be defined as needed.
<b>Values</b>	This enumeration shall minimally support following values <ul style="list-style-type: none"><li>• Context</li><li>• Topology</li><li>• Node</li><li>• Link</li><li>• Node-Edge-Point</li><li>• Service-End-Point</li><li>• Connection-End-Point</li><li>• Connectivity-Service</li><li>• Virtual Network Service</li><li>• Connection</li><li>• Path</li></ul>

454

<b>TAPI_FR 51: Notification-Source-Indicator</b>	
<b>Description</b>	Notification agents shall identify the source of notification messages.
<b>Values</b>	This enumeration attribute shall minimally support following values <ul style="list-style-type: none"><li>• ResourceOperation</li><li>• ManagementOperation</li><li>• Unknown</li></ul>

## 4 Appendix A: Transport API Concepts Overview

### 4.1 Context

An SDN controller or manager typically organizes its information and operates on that information within specific contexts. A *Context* is an abstraction that allows for logical isolation and grouping of network resource abstractions for specific purposes/applications and/or information exchange with its users/clients over an interface. Thus, *Context* defines the scope of control and naming that a particular SDN controller, manager or a client application has with respect to the information it operates on internally or exchanges over an interface. It therefore determines the makeup of the network resource abstractions within that domain of control.

More specifically, a T-API Context:

- Is defined by a set of Service-End-Points and its capabilities (capacity, layers, etc)
- Utilizes one or more shared namespace in information exchanges over the interface
- Includes *one or more top-level Topology* abstractions that are:
  - Either statically assigned by a controller or dynamically created on client request
  - Defined by a set of *Nodes* and *Links*
- Provides scope for control (create/retrieve/update/delete) of Topology abstractions
- Determines the level of abstraction exposed over an interface

To further illustrate the concept of Context, consider the simple single domain physical network example shown in Figure-2. It depicts a Network Provider (*Blue*) with two Customers (*Red* and *Green*). In this example, the network provider controller/manager has 3 *Contexts* – its own internal/admin *Context* representing all the resources under its control (Control Domain), and one *Context* per customer (*Red* and *Green*) that it shares over its interfaces. This is shown in Figure-3 & Figure-4 below. In this example, the provider exposes a single-*Node Topology* abstraction to customer *Red*, while it exposes a multi-*Node Topology* abstraction to customer *Green*.

- A Network Provider (*Blue*) with two Customers (*Red* and *Green*)
- All UNI interfaces are ETH (e.g. 10GE), I-NNI interfaces are OTU (e.g. 100G OTN)
- All PE-NE are ODU/ETH capable, while P-NE is only ODU capable

Figure 2 : Simple Physical Network Example

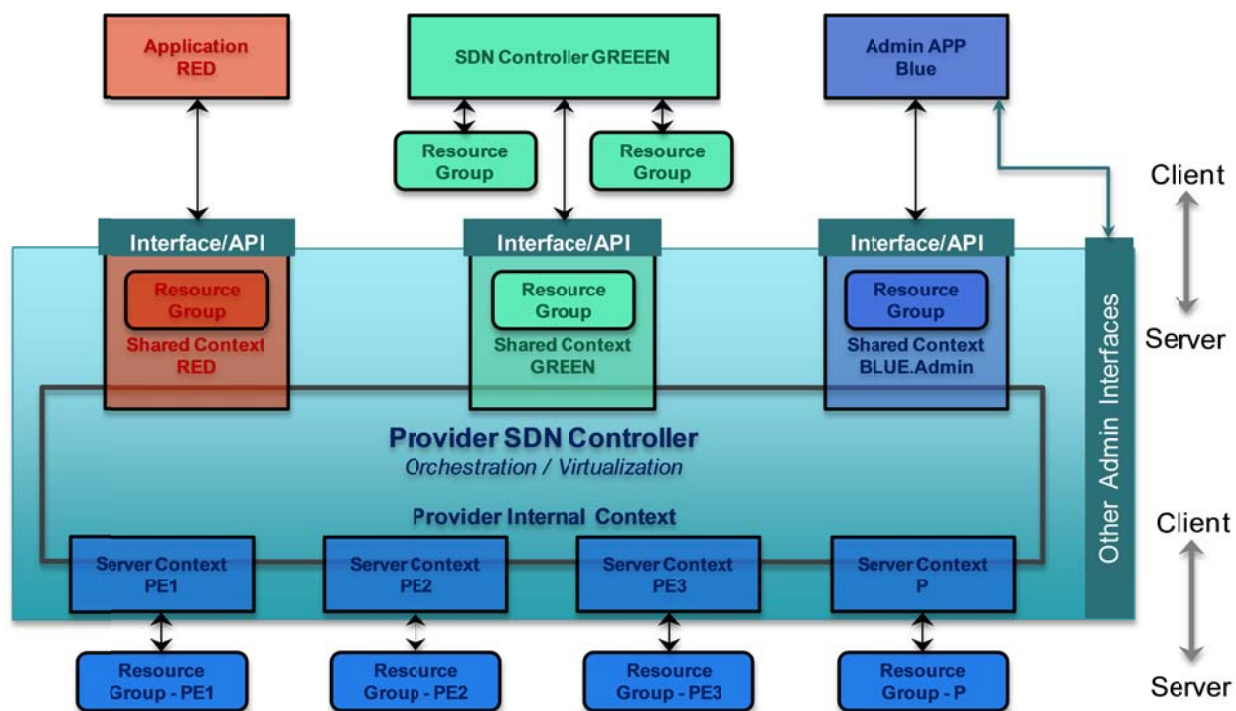

Figure 3: Shared Contexts - Architecture perspective

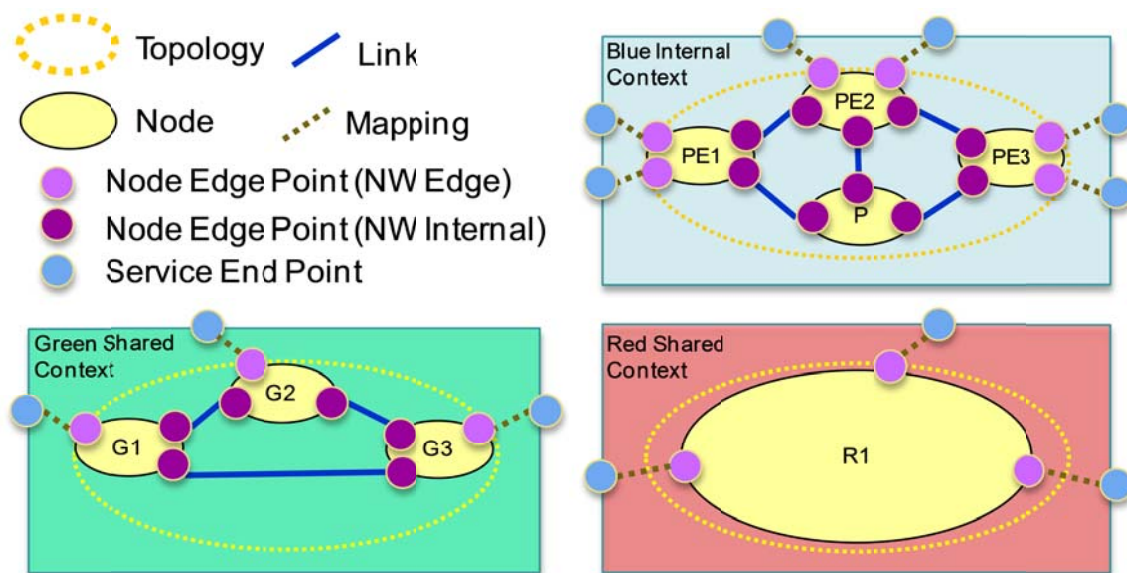

Figure 4: Shared Contexts &amp; Topology

## 4.2 Node and Topology Aspects of Forwarding Domain

The *Forwarding-Domain* represents the opportunity to enable forwarding between its edge-points. The *Forwarding-Domain* can hold zero or more instances of *Connections* and provides the context for requesting and instructing the formation, adjustment and removal of *Connections*.

The *Forwarding-Domain* supports a recursive aggregation relationship such that the internal construction of a *Forwarding-Domain* can be exposed as multiple lower level *Forwarding-Domains* and associated *Links* (partitioning).

For the purposes of API requirements, the *Forwarding-Domain* has been refactored as two separate entities:

- Node – which represents the forwarding-potential between its edge-points (*LTPs*)
- Topology – which represents the topological-aggregation of lower-level *Links* and *Nodes*

Depending on the frame of reference for an API invocation (or the position of an imaginary observer), only the opaque *Node*-aspects of a *Forwarding-Domain* would be visible (placing the observer external to the *Forwarding-Domain*) or the entire *Topology*-structure of a *Forwarding-Domain* would be visible (placing the observer internal to the *Forwarding-Domain*)

In this representation, a *Node* is a logical abstraction of forwarding capability, and as such could encompass an internal *Topology*. In such a case, a *Node* can be recursively decomposed into its lower-level *Nodes* and *Links*. So a *Node* at a top-level could abstract the *Topology* of an entire network while a *Node* at the bottom-most level could abstract a switch matrix within a device/NE.

To illustrate the concept, consider the physical network example presented in Figure-2 above. The *Node-R1* in the Red shared Context can be decomposed into a *Topology* of 3 *Nodes* *R1.1*, *R1.2*, *R1.3* and the *Links* between them, as shown in the figure below.

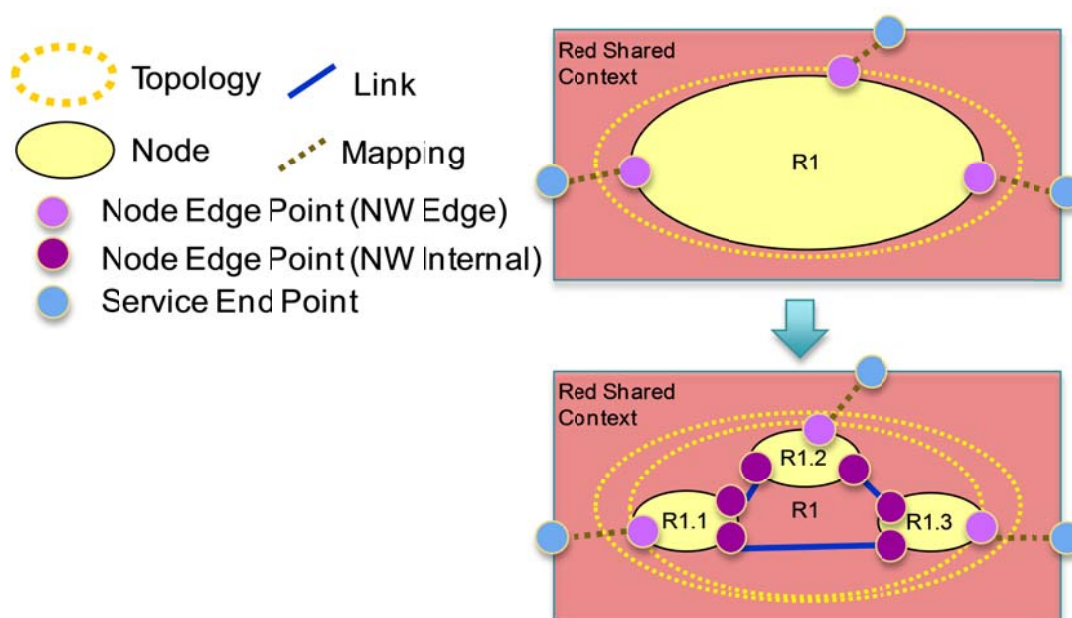

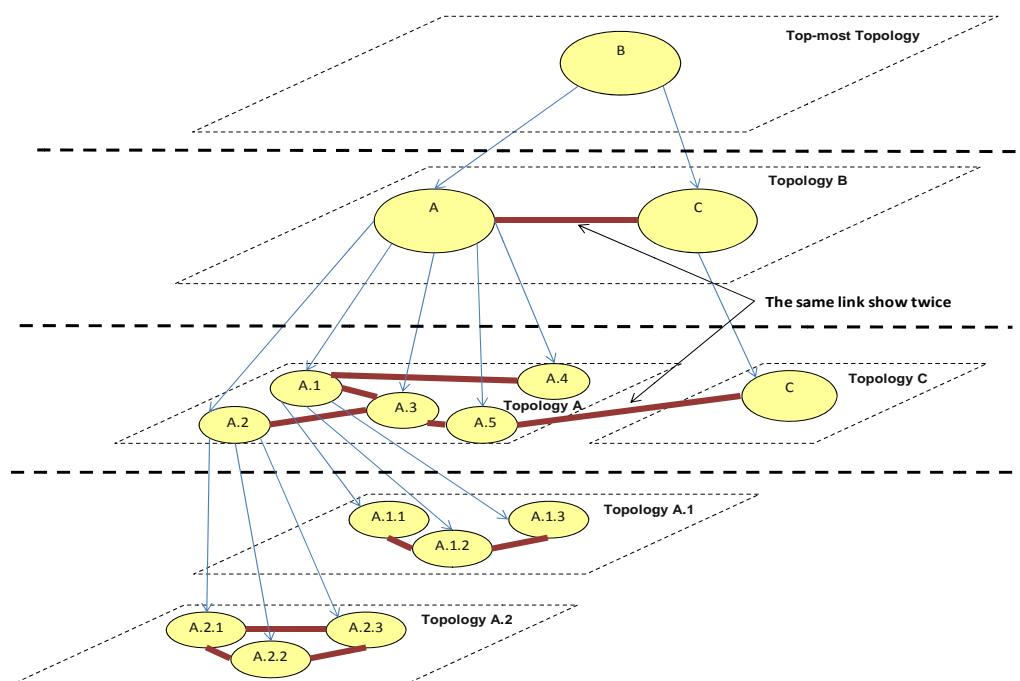

Figure 5: Topological Decomposition of Node

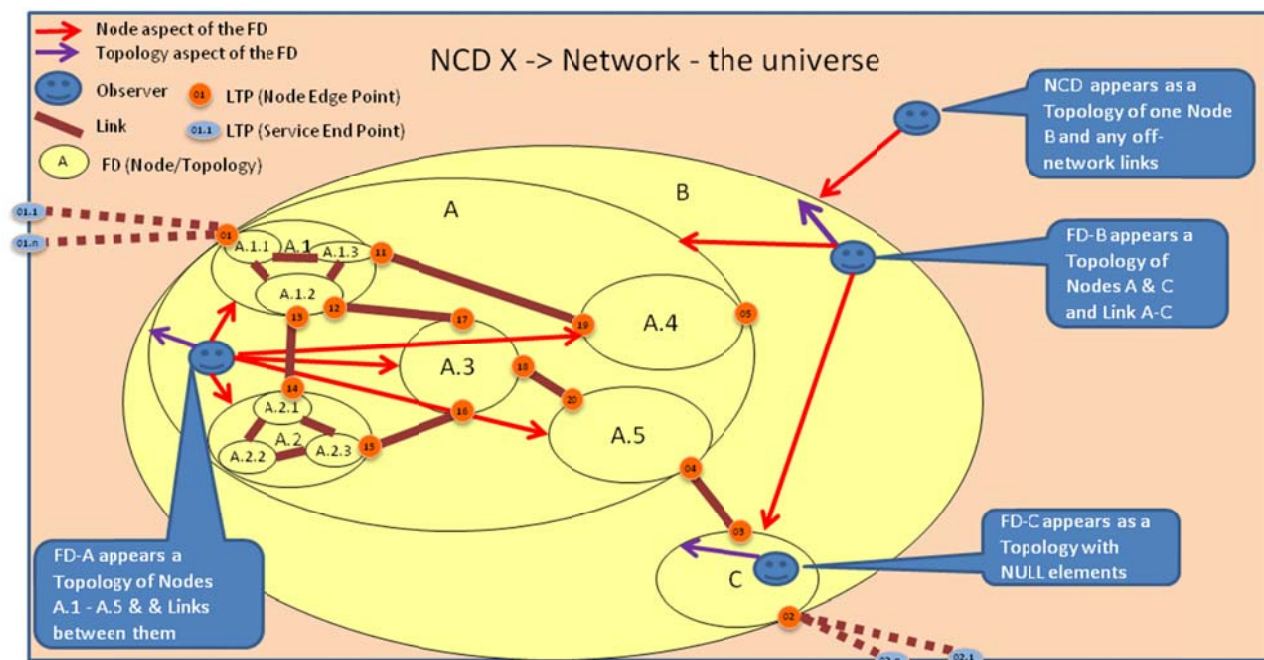

Figure-6 illustrates another example of hierarchical topology recursion from a top level topology abstraction (node B) to successively more detailed levels of topology abstraction until the lowest level of interest is reached (in this example, C, A1.1-A1.3, A2.1-A2.3).

**Figure 6: Recursive Topological Decomposition of Node**

And Figure-7 below illustrates the same network example, from the perspectives of an imaginary observer, viewing the *ForwardingDomain* from different locations within the abstraction.

**Figure 7: Node/Topology perspectives of recursively partitioned Forwarding Domain (FD)**

The effective adjacency between two or more *Forwarding-Domains* is modeled by a *Link*. In its basic form (i.e., point-to-point Link) it associates a set of *LTP* client layers on one *Forwarding-Domain* with an equivalent set of *LTP* client layers on another *Forwarding-Domain*. A *Link* may offer parameters such as capacity and delay depending on the type of technology that supports the *Link*. A *Forwarding-Domain* may aggregate *Links* that are wholly within the bounds of the *Forwarding-Domain*. A *Link* with an Off-network end cannot be encompassed by a *Forwarding-Domain*. The *Link* can support multiple transport layers via its associated *LTP* instance.

### 4.3 Hierarchical Control Domains and Contexts

The T-API *Context* is a realization of the *Network-Control-Domain* as defined in the ONF Core Information Model

In interfaces where an abstracted view of network is offered, e.g. in client/server SDN controller relationship, the *Context* defines the scope of control of the client SDN controller on the abstracted/virtual network view that has been provided by the server SDN controller. Thus *Context* relates to an abstracted view of the partitioned provider resources allocated to that particular client. In such cases, the *Context* also scopes the namespace for identifying objects representing the (virtual) resources within the (virtual) network view. The following figures illustrate few examples of *Contexts* in a hierarchical SDN controller system:

Figure 8: View of Controller-1 Context based on Views exported by Controllers 2 & 3

Figure 9: Views of Controller-2 Contexts

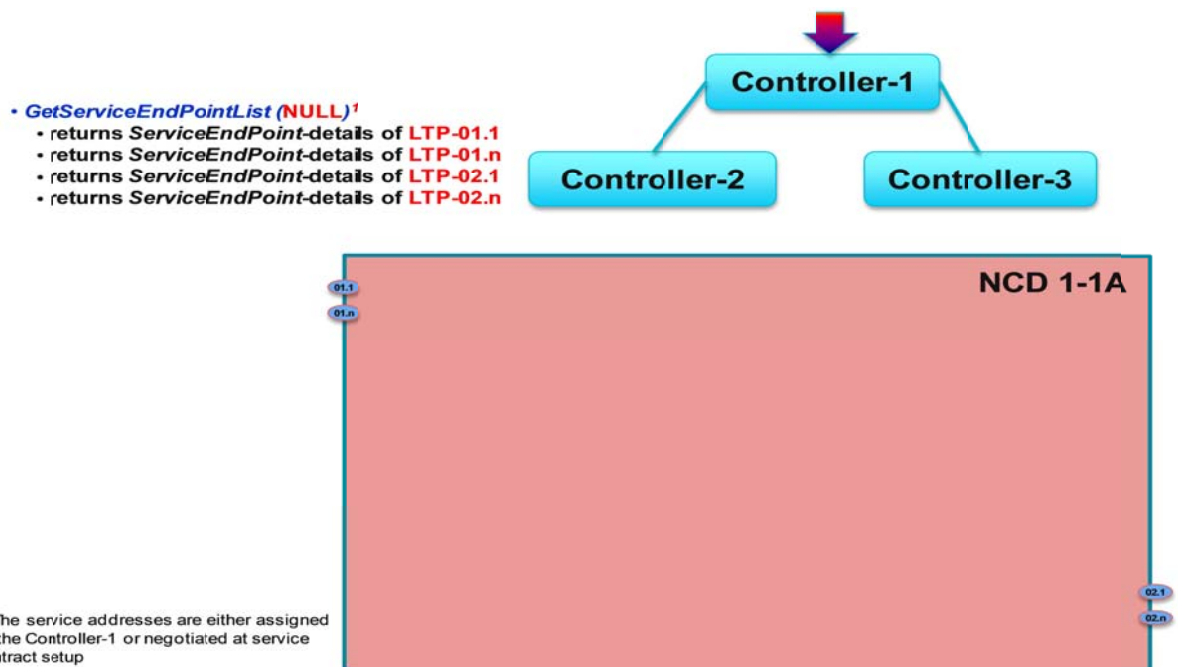

Figure 10: Views of Controller-3 Contexts

550

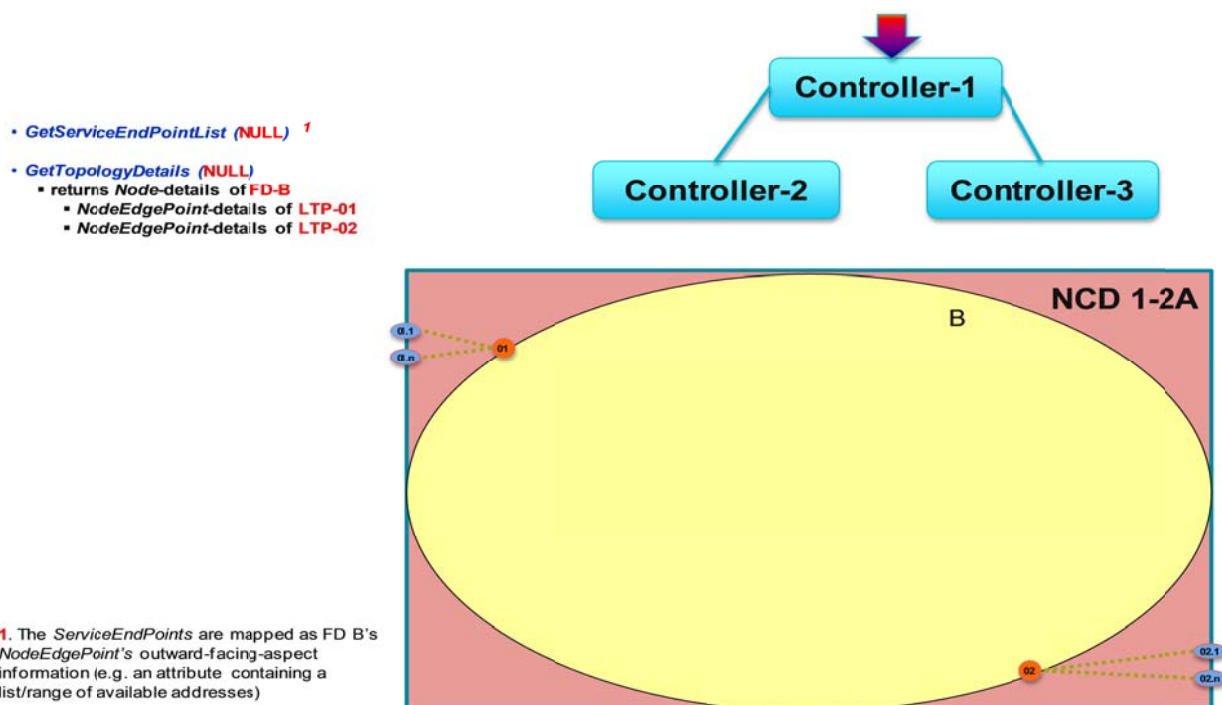

## 551 4.4 Topology Traversal using APIs

552 The following figures illustrate few examples of views of a provider topology, that a T-API  
 553 client application may obtain using the APIs.

554

  - returns Empty List

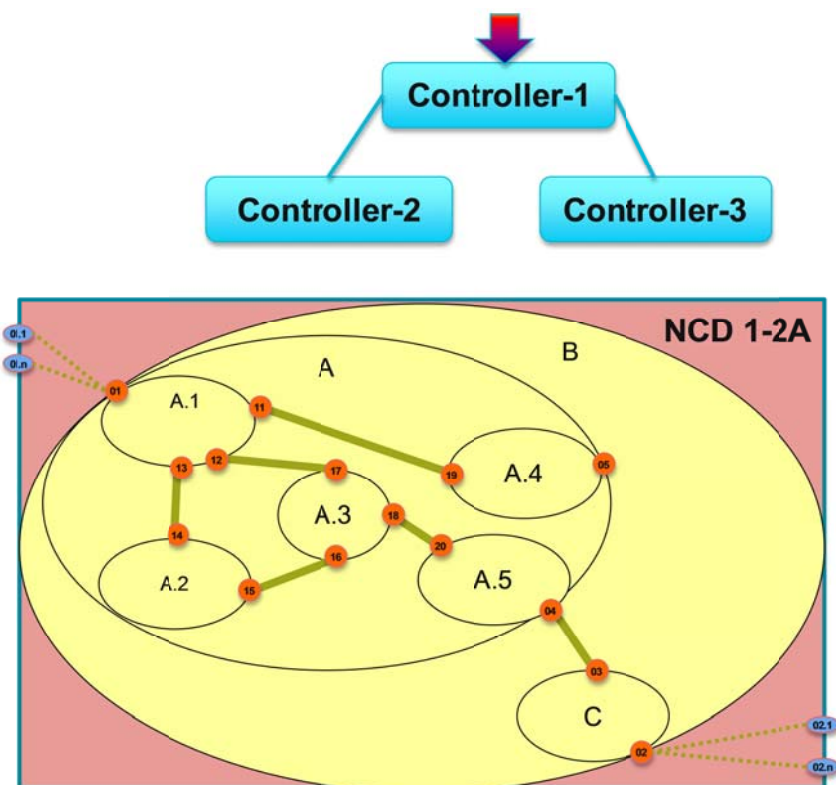

Figure 14: API Client's View of Controller-1 Context by retrieving 3 levels of Topology details

## 4.5 Service, Connection and Path

A *Service* represents an “intent-request” for connectivity between two or more *Edge-Points* (*LTPs*) exposed by the all-encompassing top-most *Forwarding-Domain* corresponding to the scope of the entire *Network-Control-Domain*. As such, *Service* is distinct from the *Connection* that realizes the *Service*. The requestor of the *Service* is expected to be able to express their intent using just an “external” view of *Forwarding-Domain* and its advertised *Edge-Points* and not require knowledge of the “internal” topology of the *Forwarding-Domain*.

The association of the *Service* to *LTPs* is made via the *Service-End-Points* which are essentially the ports of the *Service*.

The *Service* is modeled by the *Forwarding-Construct* entity defined in the ONF Core Information Model.

The *Connection* represents an enabled potential for forwarding (including all circuit and packet forms) between two or more *Edge-Points* (*LTPs*) of a *Forwarding-Domain*. A connection request typically utilizes its knowledge of the “internal” topology view of FD.

The association of the *Connection* to *LTPs* is made via *Connection-End-Points* (essentially the ports of the *Connection*) where each *End-Point* of the *Connection* has a role in the context of the *Connection*. The traffic forwarding between the associated *End-Points* of the *Connection* depends upon the type of *Connection*.

The *Connection* can be used to represent many different structures including point-to-point (P2P), point-to-multipoint (P2MP), rooted-multipoint (RMP) and multipoint-to-multipoint (MP2MP) bridge and selector structure for linear, ring or mesh protection schemes.

A *Connection* can be in only one *Forwarding-Domain*.

A *Connection* supports a recursive aggregation relationship such that the internal construction of a *Connection* can be exposed as multiple lower-level *Connection* instances (partitioning). A *Connection* can have zero or more *Paths*, each of which is defined as a list of lower level *Connection* instances. At the lowest level of recursion, a *Connection* represents a cross-connection within a switch matrix/fabric in a Network Element.

The *Connection* is modeled by the *Forwarding-Construct* entity defined in the ONF Core Information Model.

The *Path* represents the individual routes of a *Connection*. It is represented by a list of *Connections* at a lower level. Note that depending on the *Service* supported by a *Connection*, the *Connection* can have multiple routes.

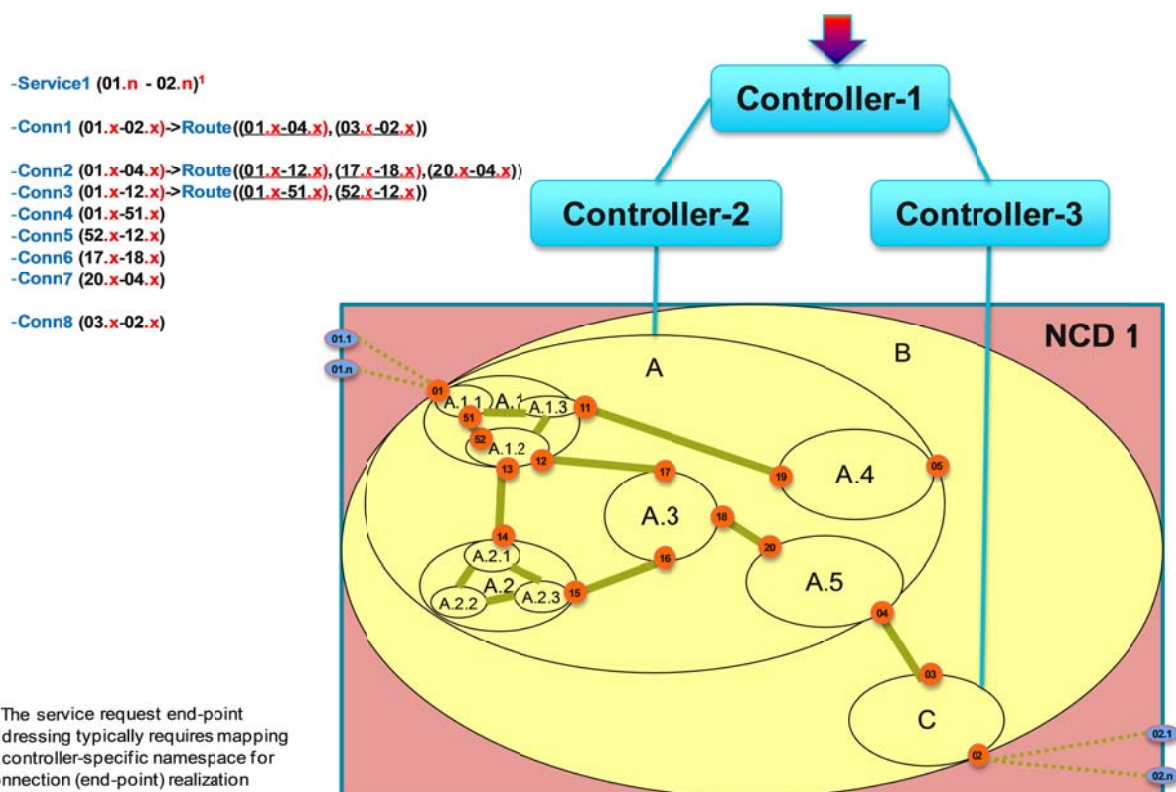

Figure 15: Service &amp; Connections from Controller-1 perspective

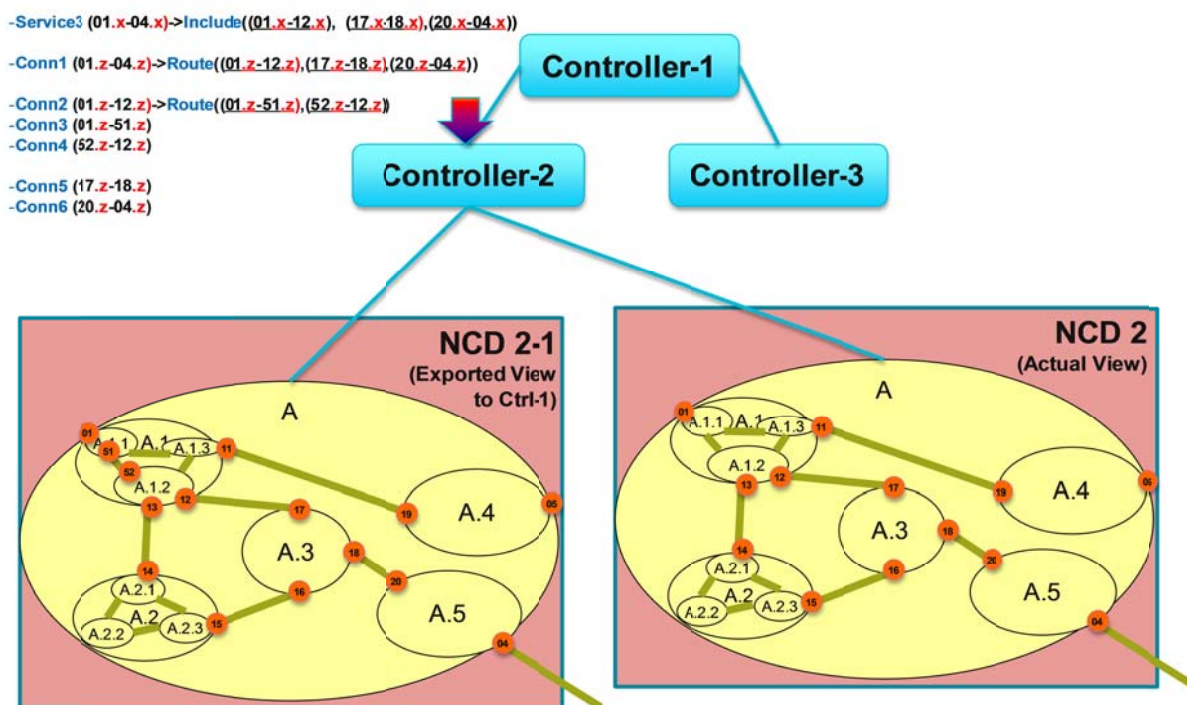

Figure 16: Service &amp; Connections from Controller-2 perspective

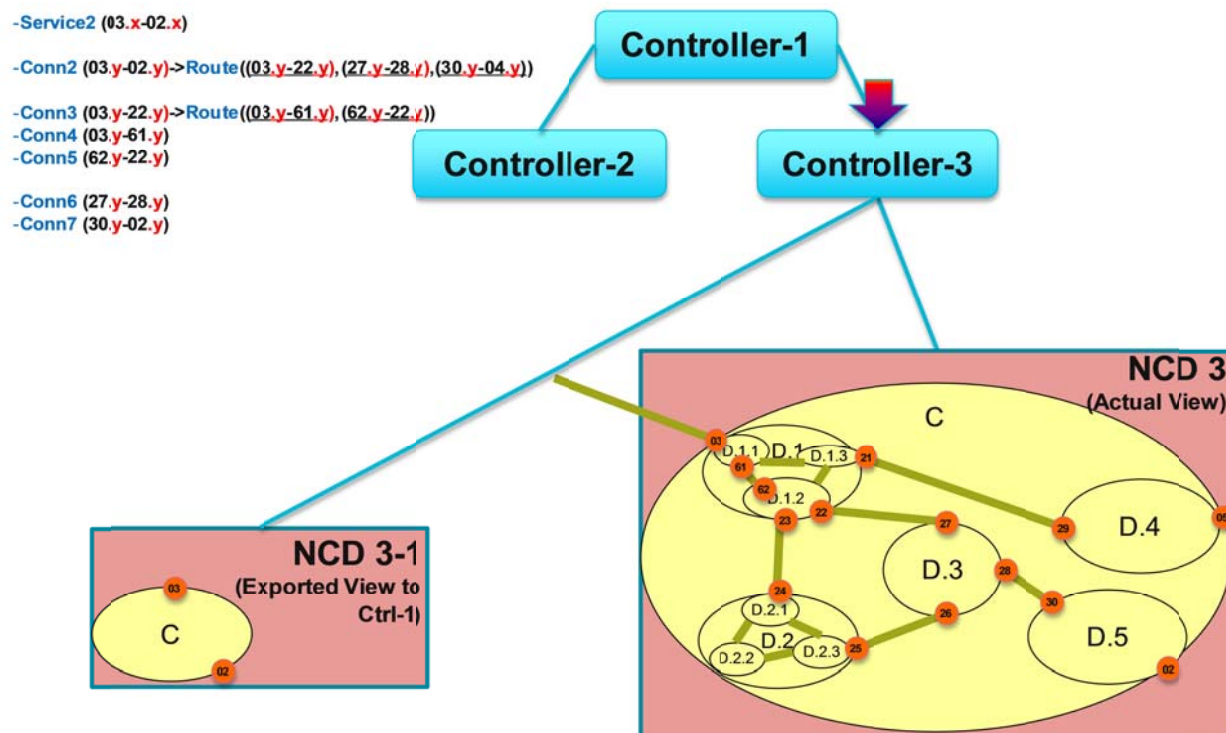

Figure 17: Service &amp; Connections from Controller-3 perspective

#### 4.6 Node Edge Point v/s Service End Point v/s Connection End Point

The *Logical-Termination-Point (LTP)* represents encapsulation of the addressing, mapping, termination, adaptation and OAM functions of one or more transport layers (including circuit and packet forms). Where the client – server relationship is fixed 1:1 and immutable, the different layers can be encapsulated in a single *LTP* instance. Where there is a n:1 relationship between client and server, the layers are split over separate instances of *LTP*.

Functions that can be associated/disassociated to/from an *Connection*, such as OAM, protection switching, and performance monitoring are referenced as secondary entities through the associated *LTP* instance.

## 5 Appendix B: Transport API Examples Use cases

Figure 13 below shows the reference physical network (“God View”) where Service Provider (SP) physical NEs (colored in blue) are interconnected each other within the SP network and three Customer Edge (CE) NEs (colored in red) are connected through the SP network.

The circles represent the “interface number” of the physical interfaces attached to each node.

The UNI links (in red) are 10GE physical links while the NNI links (in blue) are 100G OTN physical links (OTU4).

It is also assumed that the CE NEs are IP routers using the SP network to setup IP links between them.

Interface P.4 (interface number 4 of node P) is not connected to any peer NE.

It is assumed that the whole SP network is managed by a single-domain SDN controller (SP Controller).

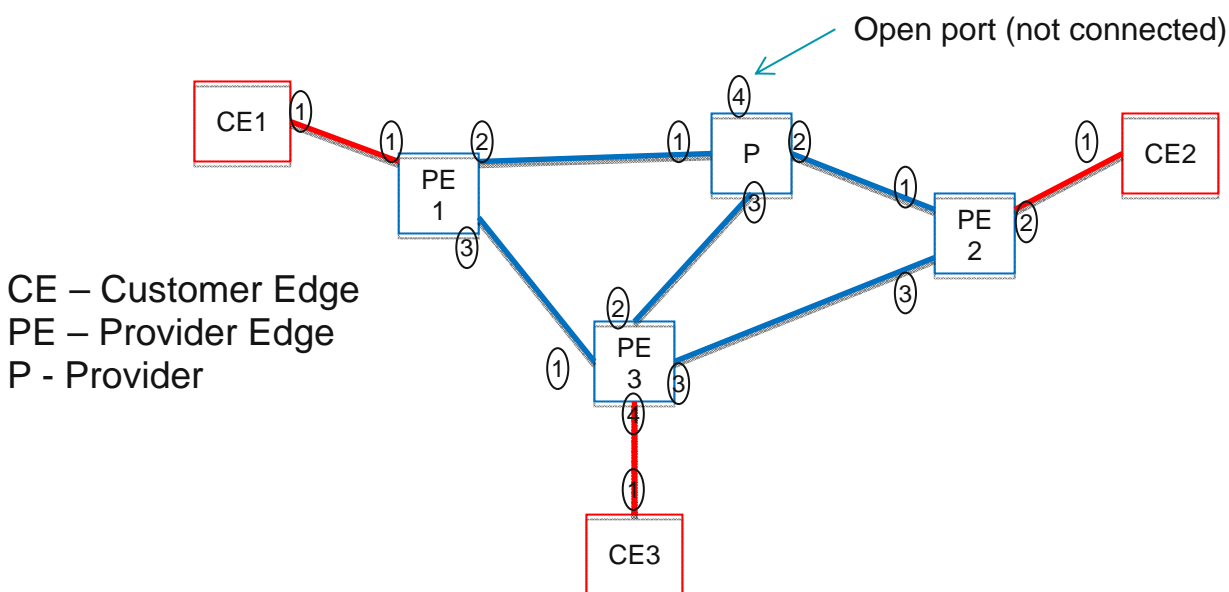

Figure 18: Example Physical Network Topology

In order to be able to setup a connectivity service, Service EndPoints, representing shared knowledge between the customer and the provider, needs to be pre-configured, based on customer and provider negotiation.

We consider three different scenarios where connectivity services can be requested:

- a) In the simplest case, there is no information about an abstract network topology shared between the client application and service provider.

In this case, only the service end points are shared knowledge.

Only the connectivity service APIs are used by the client to manage connectivity services between service end points. No path constraints can be requested in the connectivity setup request and no path information can be returned for a connection.

When a connectivity service request T-API is received, a connection controller within the service provider will internally call its path computation to setup the connection within the service provider network. This interaction is outside the scope of this document.

Topology and Path Computation T-APIs are not used between the client application and the service provider.

- b. The client application and service provider can also have shared knowledge of an abstract network topology.

The shared topology could be known a priori or retrieved via Topology API. This topology can be used to provide path constraints in the connectivity setup request and/or as a reference topology for returning the path of a connection.

The client application can internally call its path computation to derive the path constraints, based on this shared network topology view, of a connectivity setup request. This interaction is outside the scope of this document.

Path Computation T-APIs are not used.

- c. When the client application and service provider can also have shared knowledge of an abstract network topology, a further enhancement is possible.

Client application call the Path Computation T-API, with set of constraints based on abstracted NW view, to get a “list” of paths matching customer application constraints.

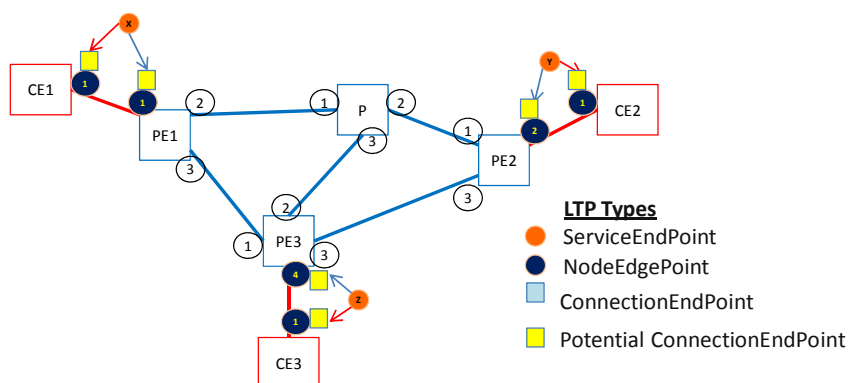

Client application can use this information to provide path constraints in the Connectivity Request Setup T-API to force the SP controller to select the path it prefers from the list returned by the Path Computation API.

This approach seems more useful in more complex scenarios e.g., a multi-domain network scenario where an orchestrator controller can request a domain controller to setup a sub-optimal path within its domain which would be part of the optimal multi-domain path.

## 5.1 10GE EPL Service over ODU2 Connection over 100G OTN network

In this use case the customer is willing to dynamically create a 10G IP Link between two of its CE routers connected to the SP network via two 10GE physical interfaces: for example an IP Link between CE1 and CE2 routers.

680 In order to support this use case in the reference network example, it is sufficient to pre-  
 681 configure three Service EndPoints: X, Y and Z such that, to create an IP Link between CE1 and  
 682 CE2, a 10GE EPL Service needs to be requested between SEPs X and Y.

683  
 684 **Figure 19: Example 10GE EPL Service over ODU2**

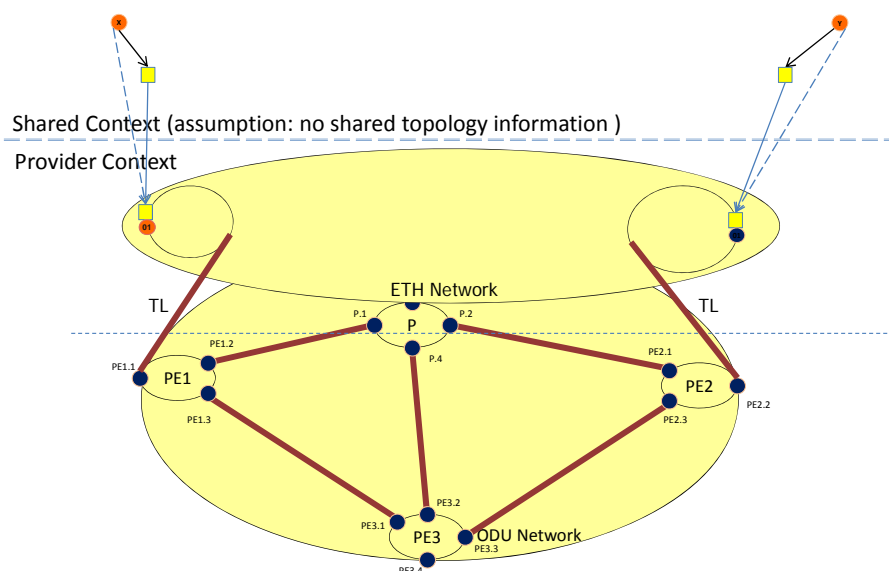

685 In the shared T-API context, X is a pool of one and only one potential L-EC (Link Ethernet  
 686 Connection, as defined in G.8021) Connection EndPoint (CEP).

687 The customer controller knows also the mapping between this potential L-EC CEP within the  
 688 shared context and the potential L-EC CEP associated to the CE1, port 1, and therefore it can  
 689 infer that the SEP X maps to that L-EC CEP within its context.

690  
 691 **Figure 20: 10G EPL - Customer View of Connectivity**

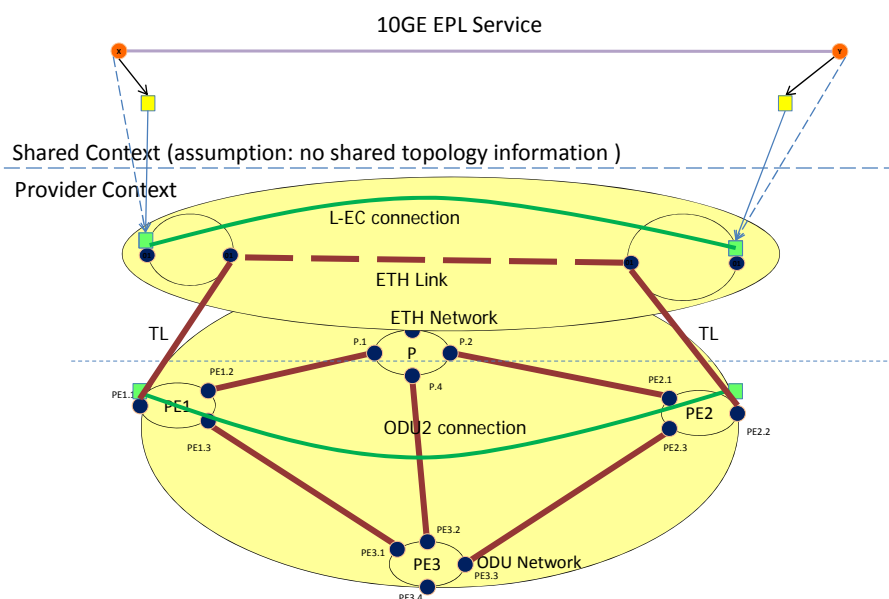

692 In a similar manner, the SP controller can infer that the SEP X maps to the potential L-EC CEP,  
 693 within its context, associated with PE1, port 1:

**Figure 21: 10G EPL - Provider's View of Topology exported to the Customer**

Similar one-to-one mappings apply to Y and Z Service EPs.

When the 10GE EPL service is requested, an L-EC (Link Ethernet Connection, as defined in G.8021.1) connection (between PE1.1 and PE2.2) within the SP network will be created:

**Figure 22: 10G EPL - Provider's View of Service/Connections exported to the Customer**

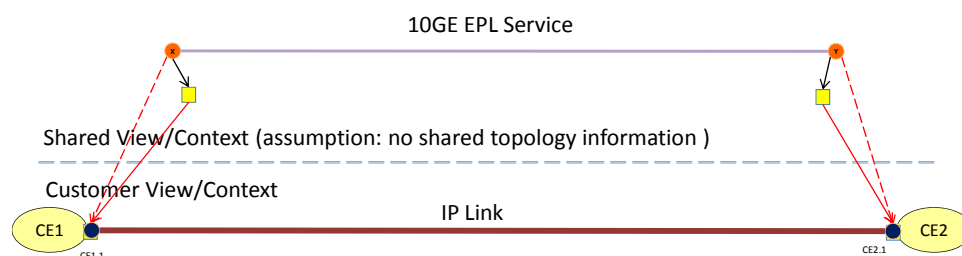

Three different implementations, within the service provider, are possible

- ODU2 connection
- Service EC (S-EC) connection
- PW connection

The choice can be based on network capability, service-provider policy, a pre-negotiated policy between customer and provider, dynamically chosen by the service provider controller e.g. based on the feedbacks from the path computation used within the SP controller.

Note – if there is a multi-layer shared abstract topology view, the path constraints of the service request can be used by the customer to constrain also the selection of the connection type. Detailed description of this use case is for further study.

As soon as the service is successfully created, the customer can create the IP Link, within the customer controller context, since there is a one-to-one mapping between the SEPs and the IP NEPs of the IP Link supported by the 10GE EPL Service:

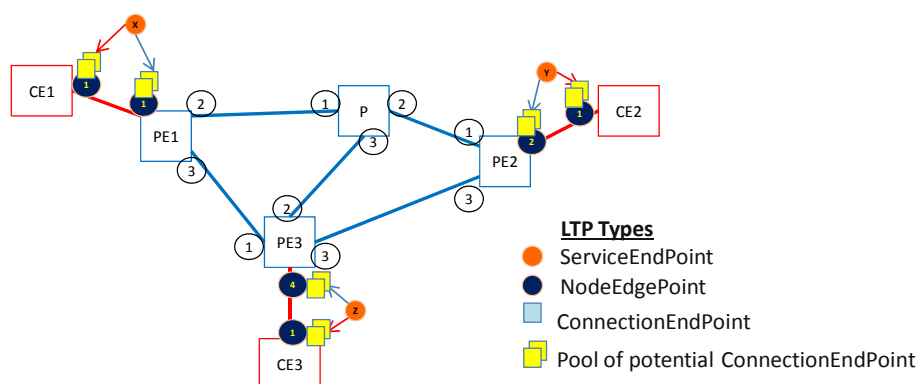

**Figure 23: 10G EPL - Customer's view of Service/Connectivity**

In this use case, there is one and only one L-EC connection within the shared context that can support the requested service. There is no need to report this L-EC connection, since it does not provide to the customer controller any additional information besides the fact that the service has been successfully setup.

## 5.2 1G EVPL Service over ODU0 Connection over 100G OTN network

In this use case the customer is willing to dynamically create a 1G IP Link between two of its CE routers, connected to the SP network via two 10GE physical interfaces which can be shared by different IP Links (using VLANs).

In order to support this use case in the reference network example, it is sufficient to pre-configure three SEPs: X, Y and Z such that, to create a 1G VLAN-based IP Link between CE1 and CE2, a 1G EVPL Service needs to be requested between SEPs X and Y.

**Figure 24: Example 1G EVPL Service over ODU0**

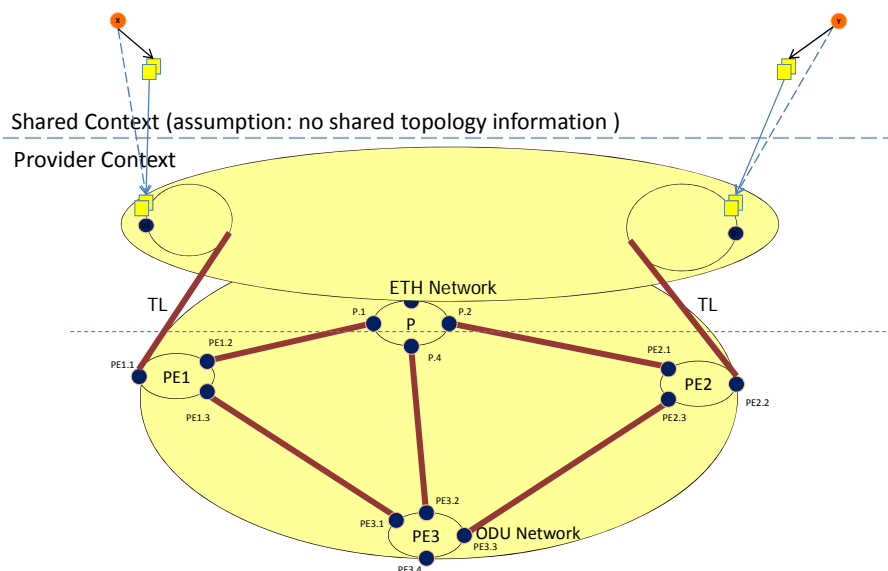

729 In the shared T-API context, X is a pool of 4k C-EC (Customer Ethernet Connection, as defined  
 730 in G.8021) potential CEPs.

731 The customer controller knows also the mapping between these 4k potential C-EC CEPs, within  
 732 the shared context, and the 4k potential C-EC CEPs as within its context, associated to the CE1,  
 733 port 1, and therefore it can infer that the SEP X maps to those 4k potential C-EC CEPs within its  
 734 context.

735  
 736 **Figure 25: 1G EVPL - Customer View of Connectivity**

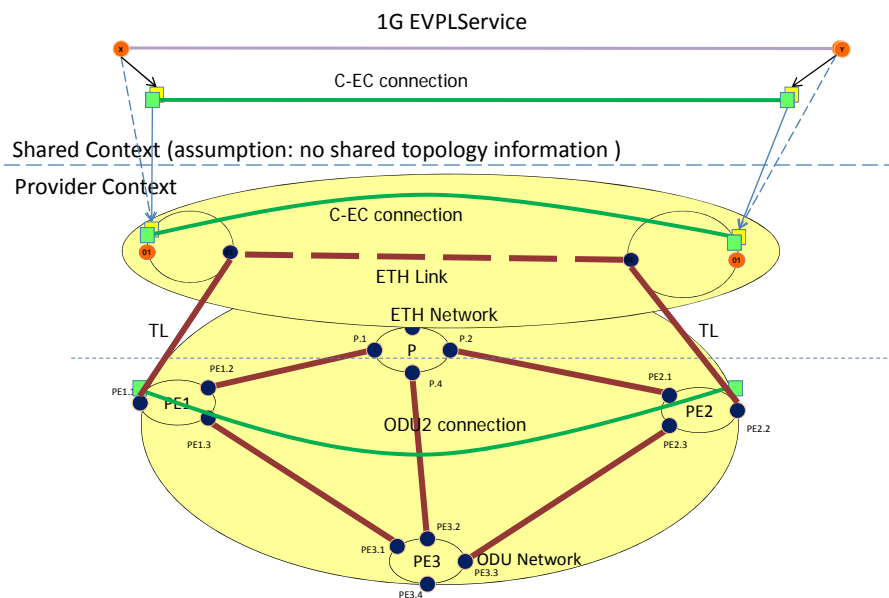

737 In a similar manner, the SP controller can infer that the SEP X maps to all the 4k potential C-EC  
 738 CEPs, within its context, associated with PE1, port 1:

739  
 740 **Figure 26: 1G EVPL - Provider's View of Topology exported to the Customer**

741 Similar mappings apply to Y and Z Service EPs.

742 When the 1G EVPL service is requested, a C-EC connection (between PE1.1 and PE2.2) within  
 743 the SP network will be created:

**Figure 27: 1G EVPL - Provider's View of Service/Connections exported to the Customer**

Three different implementations, within the service provider, are possible

- ODU0 connection
- S-EC connection
- PW connection

The choice can be based on network capability, service-provider policy, a pre-negotiated policy between customer and provider, dynamically chosen by the service provider controller e.g. based on the feedbacks from the path computation used within the SP controller.

Note – if there is a multi-layer shared abstract topology view, the path constraints of the service request can be used by the customer to constrain also the selection of the connection type. Detailed description of this use case is for further study.

As soon as the service is successfully created, the Service Provider shall also report, within the shared context, a C-EC connection between C-EC CEPs that map to the actual C-EC CEPs, within the SP network. In particular, the actual C-EC CEPs, within the shared context, provide information of the C-VLAN ID values to be used at the edge of the SP network.

Based on the C-EC connection, the customer controller can create the 1G VLAN-based IP Link, supported by the EVPL Service, between IP NEPs that map to the actual C-EC CEPs, within the shared context. In particular, the configuration of the C-VLAN ID values to be used on the IP NEPs, within the customer context, is inferred from the information in the associated actual C-EC CEPs, within the shared context.

**Figure 28: 1G EVPL - Customer's view of Service/Connectivity**

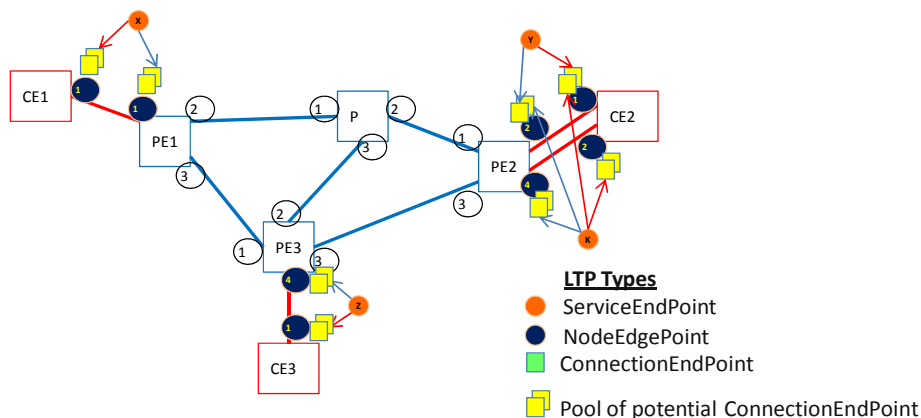

In this use case, there is many possible C-EC connections within the shared context that can support the requested service. There is a need to report, within the shared context, the actual C-EC connection implementing the requested service to provide the customer controller the information it needs to properly configure the IP NEPs within its own context (e.g., the C-VLAN ID values).

### 5.3 Var-rate EVPL Service over EVC Connection over 100G OTN network

For further study

### 5.4 EVPL Service with Load Balancing

Detailed description of this use case is for further study. This section just provides few guidelines:

**Figure 29: EVPL Service with Load Balancing**

In order to support this use case in the reference network example, in addition to the X, Y and Z SEPs, another SEP K needs to be created, such that, to create a 1G VLAN-based IP Link between CE1 and CE2, a 1G EVPL Service needs to be requested between SEPs X and K.

K is a pool of 8k C-EC potential CEPs in the shared context which, within the context of the Customer controller, maps with all the 8k potential VLAN-based IP Node EndPoints that can be created over CE2, ports 1 and 2.

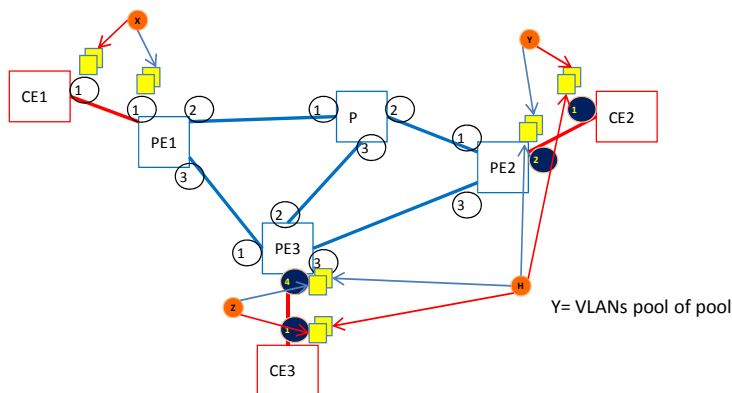

785 Within the Provider controller, these 8k C-EC potential CEPs map with all the 8k potential C-EC  
 786 CEPs associated with PE2, ports 2 and 4.

787 It is worth noting that SEPs Y and K have an overlapping set of potential CEPs.

## 788 5.5 Anycast EVPL Service

789 Detailed description of this use case is for further study. This section just provides few  
 790 guidelines:

791  
 792 **Figure 30: Example Anycast EVPL Service**

793 In order to support this use case in the reference network example, in addition to the X, Y and Z  
 794 SEPs, another SEP H needs to be created, such that, to create a 1G VLAN-based IP Link  
 795 between CE1 and either CE2 or CE3, a 1G EVPL Service needs to be requested between SEPs X  
 796 and H.

797 H is a pool of 8k C-EC potential CEPs in the shared context which, within the context of the  
 798 Customer controller, maps with all the 8k potential VLAN-based IP Node EndPoints that can be  
 799 created over CE2, port 1 and CE3, port 1.

800 Within the Provider controller, these 8k C-EC potential CEPs map with all the 8k potential C-EC  
 801 CEPs associated with PE2, port 2 and PE3, port 1.

802 It is worth noting that SEPs Y and Z K have overlapping set of potential CEPs with SEP H.

803

## 6 Appendix C: Multi-layer and Multi-domain Use cases

This section gives the usage examples of TAPI information model and API in multi-layer and multi-domain network.

We assume a multi-layer and multi-domain network configuration as shown in the following figure. The network elements are packet OTN equipments. The network contains two domains, domain A and domain B, which are controlled by Controller-2 and Controller-3 respectively. Controller-1 controls the overall network (domain C) through Controller 2 and 3. Domain A and B are interconnected with OTU-4 links. The edge ports that connect to the client equipments are 10GE Ethernet ports.

An example service of 1GE EVPL over ODU0 (multi-layer and multi-domain service) between ServiceEndPoint 1 and ServiceEndpoint 2 is requested in this network.

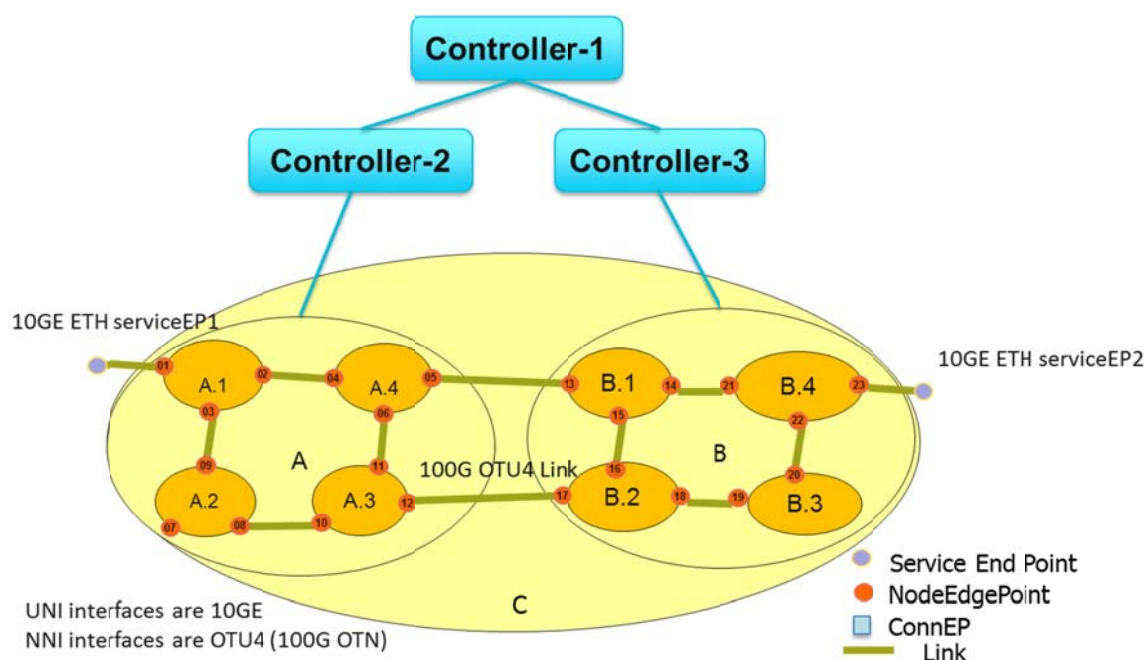

Figure 31: Multi-layer and Multi-domain Example Network Configuration

### 6.1 Multi-layer and Multi-domain Topology Initialization

We assume that all the 3 controllers are within one service provider's scope, so that all the internal topology in domain A and B are exposed to Controller 1. Since this is a multilayer network, there should be two topology instances for Ethernet and ODUk respectively. The two layer topologies are interconnected with transitional links between internal Ethernet port and ODU port (NodeEP 24, 25, 26, 27) inside node A.1 and B.4 (as shown in the following figure). This multi-layer topology enables cross-layer route computation in the controller. The serviceEndpoints at domain boundaries (serviceEP 3 and 4) should be instantiated for cross-domain service setup.

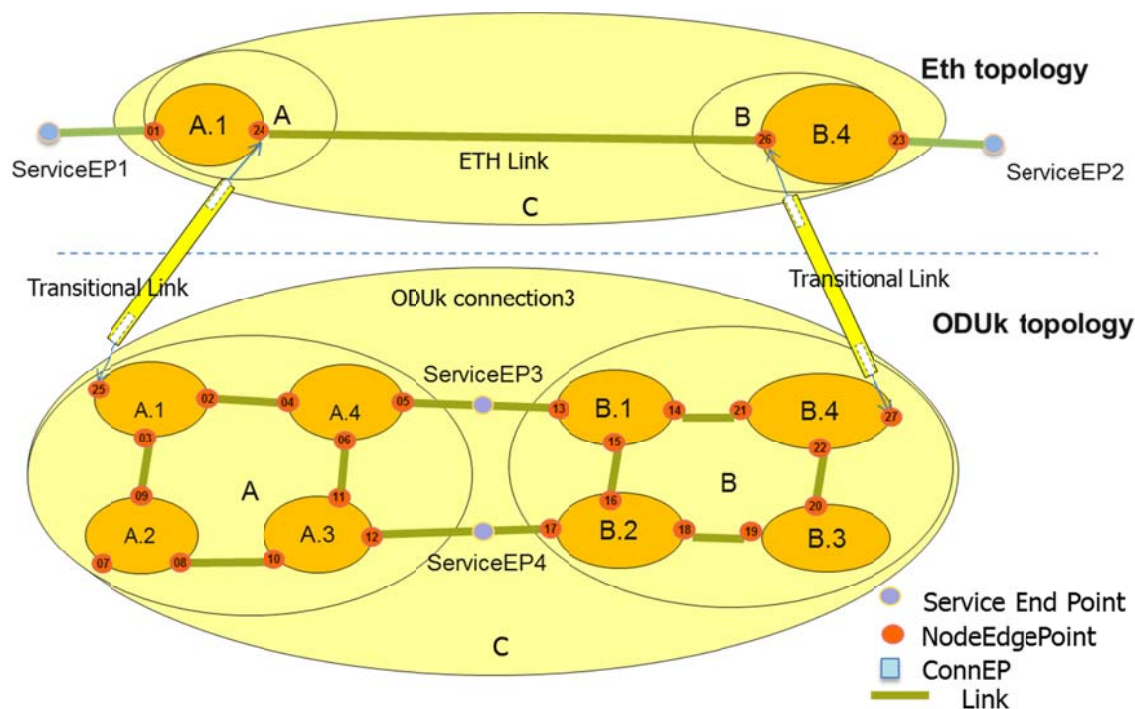

Figure 32: Network Topology in Controller 1

## 6.2 Multi-layer and multi-domain services/connections

To setup Ethernet over OTUk service in this multi-domain and multi-layer network, there are two options.

Option A: Setup multi-layer services within each domain.

This option allows controller 1 to send multi-layer service request to its subordinate controllers (Ethernet serviceEP to ODUk ServiceEP). The following are the API message exchange between controller 1 and controller 2, 3.

1. User sends ETH Connectivity Service Request to Controller 1.
2. Controller 1 receives ETH Connectivity Service Request.
3. Controller 1 computes multi-layer and multi-domain path using its knowledge of overall topology.
4. Controller 1 sends multilayer Connectivity Service 1 Request (between Ethernet serviceEP 1 to ODUk ServiceEP 3) to Controller 2.
5. Controller 2 receives multi-layer Connectivity Service Request from Controller 1.
6. Controller 2 computes multilayer path, and selects the internal NodeEPs for connection setup.
7. Controller 2 creates ODUk connection 1 and ETH connection 1 internally and returns them to Controller 1.

8. Controller 1 sends multilayer Connectivity Service 2 Request (between Ethernet serviceEP 1 to ODUk ServiceEP 3) to Controller 3.
9. Controller 3 receives multi-layer Connectivity Service Request from Controller 1.
10. Controller 3 computes multilayer path, and selects the internal NodeEPs for connection setup.
11. Controller 3 creates ODUk connection 2 and ETH connection 2 internally and returns them to Controller 1.
12. Controller 1 creates end-to-end ODUk connection 3 internally based on the received ODUk connection 1 and 2.
13. Controller 1 creates ETH link internally between A.1 and B.4 on top of connection 3.
14. Controller 1 creates the requested end-to-end ETH connection 3 based on the received ETH connection 1, 2 and ETH link internally.
15. Controller 1 returns ETH service to User.

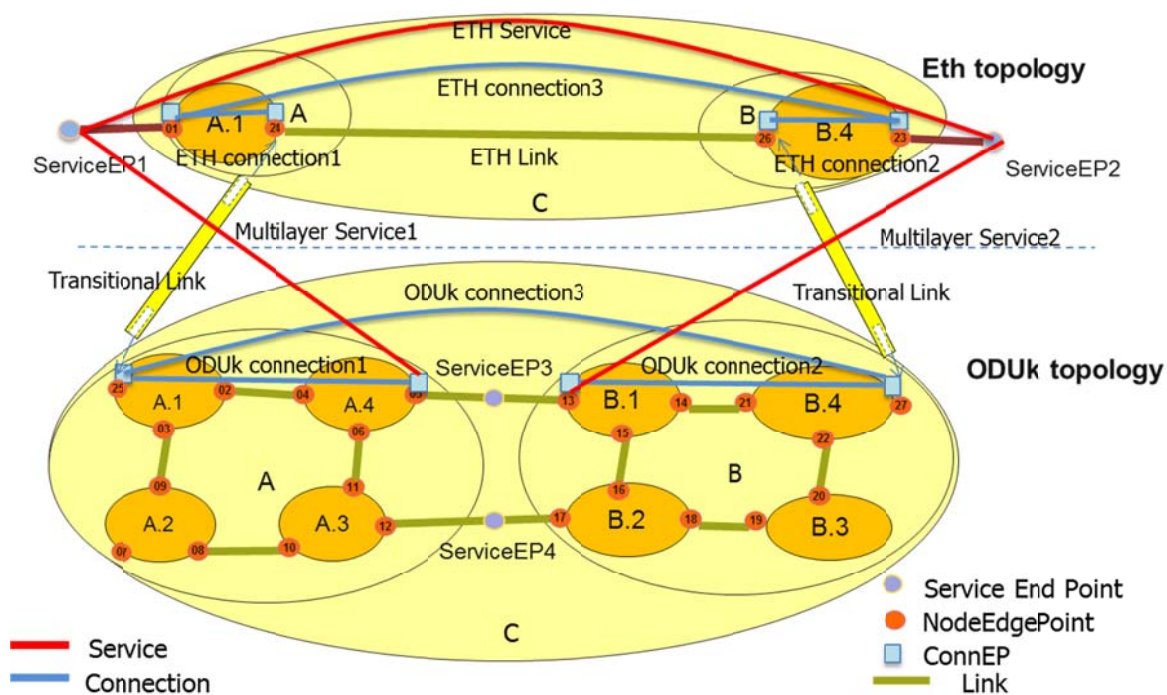

Figure 33: Multi-layer and Multi-domain service/connection setup (Option A)

Option B: Setup single-layer services within each domain.

This option only allows controller 1 to send single layer service request to its subordinate controllers. The following are the API message exchange between controller 1 and controller 2, 3.

- 866 1. User sends ETH Connectivity Service Request to Controller 1.
- 867 2. Controller 1 receives ETH Connectivity Service Request.
- 868 3. Controller 1 computes multi-layer and multi-domain path using its knowledge of overall  
869 topology.
- 870 4. Controller 1 sends ODU Connectivity Service Request (between ServiceEP3 and NodeEP  
871 26) to Controller 2. (NodeEP 26 should also be assigned a serviceEP).
- 872 5. Controller 1 sends ETH Connectivity Service Request (between ServiceEP1 and NodeEP  
873 24) to Controller 2. (NodeEP 24 should also be assigned a serviceEP).
- 874 6. Controller 2 creates requested ODUk connection 1 and ETH connection 1 internally and  
875 returns them to Controller 1.
- 876 7. Controller 1 sends ODU Connectivity Service Request (between ServiceEP3 and NodeEP  
877 27) to Controller 3. (NodeEP 27 should also be assigned a serviceEP).
- 878 8. Controller 1 sends ETH Connectivity Service Request (between ServiceEP2 and NodeEP  
879 28) to Controller 3. (NodeEP 28 should also be assigned a serviceEP).
- 880 9. Controller 3 creates requested ODUk connection 1 and ETH connection 1 internally and  
881 returns them to Controller 1.
- 882 10. Controller 1 creates end-to-end ODUk connection 3 internally based on the received  
883 ODUk connection 1 and 2.
- 884 11. Controller 1 creates ETH link internally between A.1 and B.4 on top of connection 3.
- 885 12. Controller 1 creates the requested end-to-end ETH connection 3 based on the received  
886 ETH connection 1, 2 and ETH link internally.
- 887 13. Controller 1 returns ETH service to User.
- 888

Figure 34: Multi-layer and Multi-domain service/connection setup (Option B)

### 6.3 Topology after service/connection Setup

After service and connection setup, the related connectionEndPoints and internal connections will be created. The following figure gives an example topology instance diagram of node A.1 after the EVPL service/connection setup. S-VLAN ConnEP in this figure is optional based on vendor implementation.

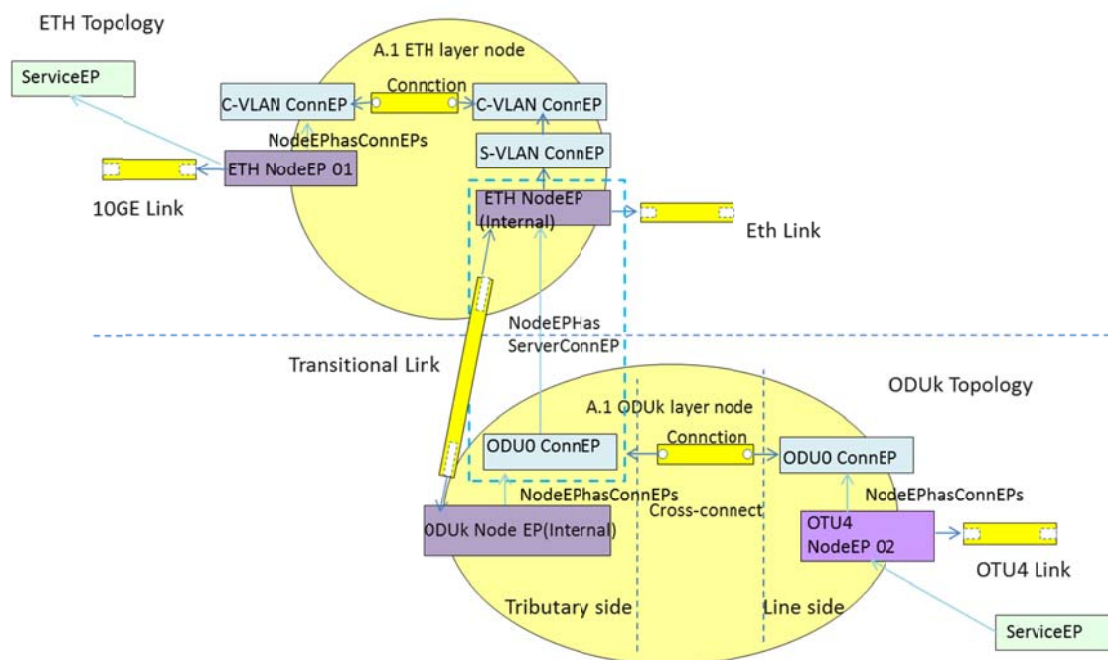

Figure 35: Topology instance diagram after service/connection setup

898 **6.4 Further work**

899 Multi-domain protection and multi-domain P2MP/MP2MP service use cases are for further study.
